Foreword

I am proud to present the 2006 – 2010 BreastScreen Statistical Report. This Report demonstrates the service's commitment to providing safe and effective quality screening and assessment services to the women of Western Australia.

Breast cancer is a major cause of mortality for women. The life time risk of developing breast cancer is considered to be as high as one in eight women. Although considerable research has been undertaken, the cause of breast cancer remains unidentified and there is no known method of prevention for this disease. Our best hope of reducing the impact of breast cancer is by targeting those women at higher risk and providing population based mammographic screening in order to detect cancers in their early and most treatable stages. The BreastScreen Australia Evaluation Report, released in 2009, demonstrated that population screening in Australia has led to a 28% reduction in breast cancer mortality since 1991.

BreastScreen WA is facing numerous challenges in the next five to ten years with anticipated increases in demand due to an enlarging ageing population, significant advances in medical imaging technology, information technology, an ageing workforce and substantial organisational changes within the public health system.

The period of 2006 to 2010 was a busy time for BreastScreen WA. The service celebrated its 20th anniversary in 2009 and performed its one millionth examination in 2007. BreastScreen WA applied for re-accreditation in 2007 and was awarded 4 year accreditation with commendation.

The service looks forward in the short term to the challenges and rewards of converting from hard copy film reading to soft copy reading. BreastScreen WA would like to thank the Commonwealth of Australia for the support they have provided through the Health and Hospital Fund, and the West Australian Department of Health Medical Equipment Replacement Fund, both of which have allowed the service to replace 18 analogue mammogram machines with full field digital equipment. The funding has also allowed BreastScreen WA to replace four mobile vans and progress with the picture archiving communication system (PACS) development. Future challenges also include the opening of the new Bunbury screening and assessment clinic in conjunction with the St John of God Hospital Regional Cancer Centre. The opening of the Fiona Stanley Breast Clinic in 2014 will provide the service with much needed increased assessment capacity.

I know that progress for the program and the fulfilment of the service's goals are possible only due to each employee's commitment, professionalism and determination to reduce the impact of breast cancer on the lives of our clients and their families. The management team continues to commit to enhancing the screening program and identifying opportunities for continuous improvement to allow BreastScreen WA to achieve its continuing aim of reducing the adverse impact of breast cancer in the Western Australian community.

The outstanding achievements presented in this Report are thanks to the contribution of all members of the service workforce, from screening to administration to assessment, and I would like to thank them all for their dedication and commitment to BreastScreen WA. I would also like to offer a special thanks to members of the committees of internal stakeholders which support the Program, such as the Consumer Reference Group, the Aboriginal Women's Reference Group, the GP Advisory Committee and the State Accreditation Committee.

Dr Liz Wylie
Medical Director
October 2012

The Program

BreastScreen WA is a joint Commonwealth – State program and a partner in the national BreastScreen Australia program, whose aim is to reduce mortality and morbidity from breast cancer through detection of the disease in its early stages. Due to medical evidence demonstrating the greatest benefits of screening mammography to women aged 50 to 69 years, the service targets this age group, while allowing all West Australian women aged over 40 years to attend the program.

To ensure the highest standard of service and care to all women who take part in the program, BreastScreen WA operates within the framework of a set of minimum standards and requirements for accreditation within the National Program. This set of core standards and performance targets is known as the National Accreditation Standards, and includes all aspects of service provision such as participation and recall rates, cancer detection rates, clinical practices, staff training, data management and consumer satisfaction. These standards utilise a quality improvement approach to all aspects of screening and assessment.

From its establishment in 1989 as part of the pilot program to evaluate national mammography screening, BreastScreen WA has expanded to 10 fixed site clinics and 4 mobile units. The service is available to women at clinics in Cannington, Fremantle, Perth City, Mirrabooka, Midland, Joondalup, Padbury, Rockingham, and Bunbury and within the David Jones store in Perth. The David Jones Rose Clinic, opened in September 2012, is a new initiative in conjunction with the retailer. Rural and remote areas of the WA are visited every two years by one of the four mobile units (see Maps).

The administration of the service is carried out at the State Coordination Unit (SCU) in Perth. Staff here are responsible for planning and management of the screening service, screening appointment bookings, recruitment and assessment clinic booking, in addition to provision of film reading, file management, data handling and all client invitation, reminder and results letters. The reporting of all financial aspects of the program, monitoring and reporting of service performance and promotional material creation and distribution also occurs from this central location.

Women recalled for suspicious screen-detected lesions can attend one of the BreastScreen WA multidisciplinary assessment centres at Royal Perth Hospital or Sir Charles Gairdner Hospital. Country clients may have their initial work up, using diagnostic mammographic views of the lesion, performed on the mobile unit. Specialist breast nurses at the SCU inform women and their general practitioner of the need for assessment and will organise appointments at the program assessment centres. They also offer support and advice to women regarding their assessment visit.

In 2012 the service completed transition from analogue to full field digital mammography x-ray equipment and by late 2013 will be fully digital in terms of reading and storing all screening and assessment images. These innovations will allow for greater service capacity and easier workflows for the radiographers, along with changes to the way images are stored and read. New mobile vehicles were purchased to house the sensitive digital equipment and are already travelling the State in their new livery.

Early in 2013 the Bunbury clinic will be transformed into a screening and assessment service, located in the South West Health Campus in partnership with the Bunbury St John of God Hospital. A future fourth site for a multidisciplinary assessment clinic is planned for the new Fiona Stanley Hospital in Murdoch, due for completion in 2014.

The next two years will see further changes in the way the service manages its workflow and procedures to suit the digital age and meet the demands of a growing target population. Changes to the Program at a national level, driven by a review conducted by BreastScreen Australia in 2008, will also provide challenges to BreastScreen WA in the coming years. Service planning is an ongoing part of BreastScreen WA activities, and is already underway to complete the transition to digital mammography with online digital image reading and to devise innovative solutions to the challenges ahead.

Program Highlights 2006 to 2010

- A new policy covering women with a family history of breast cancer was launched in March 2006, aimed at minimising unnecessary x-ray exposure for women who were not at higher risk of breast cancer. Annual screening for family history is now recommended only for women with a significant family history of breast cancer.
- The Cannington clinic, the service's oldest, was relocated to new and larger premises which would eventually allow for a third x-ray machine to cater for demand at this popular clinic.
- BreastScreen WA was contracted by the Commonwealth to conduct biennial mammography screening at Christmas Island in August 2006. The radiographer spends two weeks on the Island and images are transferred to Perth for reading.
- In February 2007 the service was awarded 4 years accreditation with commendation by the national program.
- In June 2007 the service began using SMS messaging to remind women of their appointment time and date.
- BreastScreen WA extended the off-shore mammography screening for the Commonwealth to the Cocos Islands in August 2007.
- The service performed its one millionth screening examination in December 2007.
- The 4th BreastScreen WA Multidisciplinary Conference "Digital and Magnetic Resonance Breast Imaging" was held on the 24-25th May 2008.
- In 2008 the service took part in the BreastScreen Australia evaluation, which aimed to review the current governance and management arrangements of the Program and evaluate the current model to identify opportunities for improvement.
- A new clinic was opened in March 2008 at Blackwattle Parade, Padbury, to cater for the growing demand in the north-western Perth suburbs.
- In March 2009 BreastScreen WA celebrated 20 years of delivering the breast cancer screening program.
- The 5th BreastScreen WA Multidisciplinary Conference "Breast Screening – a sustainable future" was held in Perth in October 2010.
- A Substantive Equality Report was prepared for the Equal Opportunity Commission in 2010 and the service was commended for its progressive and 'best practice' approach to service delivery amongst Indigenous and ethnic minority groups.

Participation in the Program

Participation rates

NAS 1.1.1: ≥ 70% of women aged 50–69 years participate in screening in the most recent 24-month period.[1]

The BreastScreen WA program aims to minimise mortality and morbidity due to breast cancer in the population of women who will get the most benefit from screening, those in the target age group of 50 to 69 years. To achieve this, at least 70% of these women should participate in the program at least once over a two-year period.

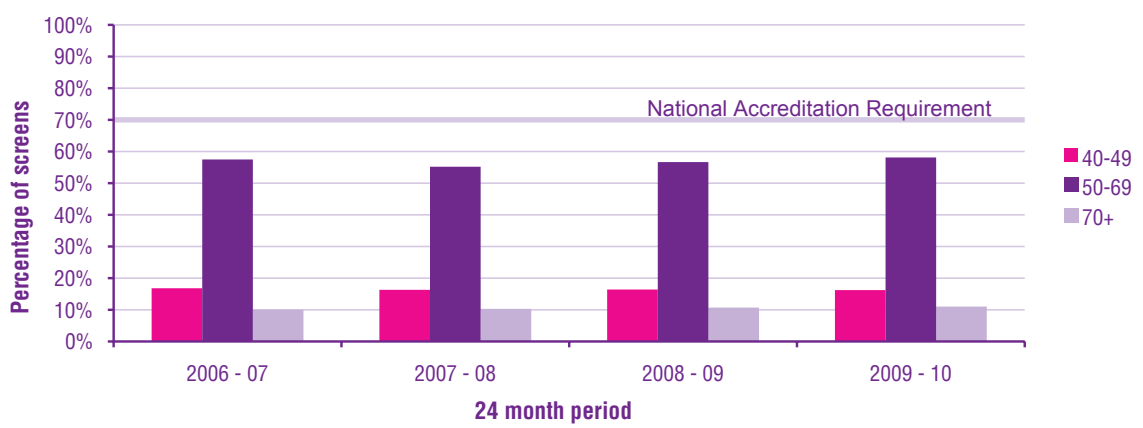
Women attend the program after receiving an invitation letter if they are on the electoral roll, or a reminder letter to return for a rescreen. If women due for a rescreen do not respond they are sent a reminder letter one month, and again one year, later. Invitations for the first screen, based on the electoral roll, are sent to those aged between 50 and 69 years. Women who have made a booking are sent an appointment SMS reminder to their mobile phone; those who have not responded to their rescreen letter also get a SMS reminder to make a booking.

Significant efforts are put into promoting the program and the benefits of regular screening, with pamphlets, a website containing informative material and information for downloading, community-focussed presentations, attendance at community events and shopping centres, inter-agency collaboration, liaison with General Practitioners, and provision of materials for those with language difficulties and assistance for those with special needs. BreastScreen WA aims to make the service equitable to all eligible women in Western Australia.

Population data is taken from the Australian Bureau of Statistic's yearly estimated resident population, averaged over a 24-month period. The population of women in WA aged 40 years and over has steadily increased from 468,615 women in 2006-2007 to 507,178 women in 2009-2010. Such a growth rate poses challenges for the service as both capacity and encouragement to screen must be addressed to meet the participation rate standard.

In the 24 month period 2009-2010, 140,680 women aged 50 to 69 years were screened of a total target age population of 178, 331 (Table 1). This represented a participation rate of 58%, the highest rate achieved since the start of the program. By comparison, the current average national participation rate across all services was 55% in 2009-2010.

Figure 1: Participation of women by age group



[1] BreastScreen Australia National Accreditation Standards (NAS) as part of the national accreditation and quality improvement program 2004

The pattern of participation differed between women resident in country and metropolitan regions in this 5 year period. Participation rates of women living in the metropolitan area have increased, whilst rates in country areas have fallen, and by 2009/2010 they had exceeded that of women in country areas for the first time (Figure 2). Over this period screening capacity had increased in the metropolitan area with the relocation of the Cannington Clinic to larger premises in 2006, the opening of a new metropolitan clinic in Padbury in 2008 and, also in 2008, a new fixed site clinic at Rockingham which replaced a mobile service in that area.

Figure 2: Participation of women aged 50-69 by place of residence

Women attending for rescreens

NAS 1.2.1: ≥ 75% of women aged 50–67 years who attend for their first screen within the Program are rescreened within 27 months.

NAS 1.2.2: Of women aged 50–67 years participating in their second and subsequent rescreens within the Program, ≥ 90% are rescreened within 27 months of their previous screening episode.

Regular mammographic screening at two-yearly intervals is the best way to ensure early detection of breast cancers. A high rescreen rate indicates that the repeat screening message is being heeded.

For women aged 50 to 67 years, for the period 2004 to 2008, the rescreen rate for first screens averaged 60% and for subsequent screens averaged 78%.

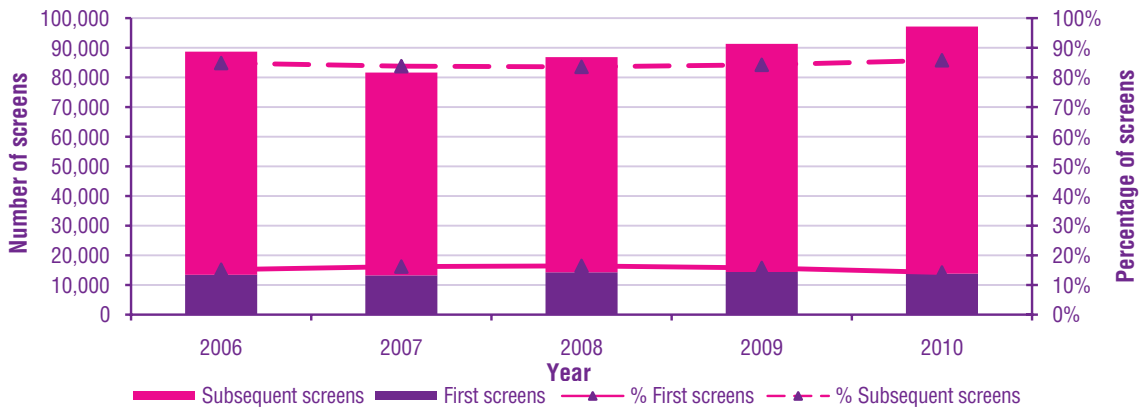
For women aged 50 to 69 years the average rescreen rate for first screens over the 5 years was 60% but for subsequent screens the average was 75%. The figures relate to the index year in which the women were previously screened (Table 3).

Figure 3: Rates of rescreen within 27 months of previous screen in women aged 50-69 years

Attendance rates by screening round

In 2007 there was a drop in total attendances in the Program, coinciding with capacity constraints at that time. The service responded by opening new fixed site clinics and expanding premises, as noted above. The total number of women screened annually subsequently increased, reaching 97,159 women in 2010 (Table 4). In general, the proportion of subsequent screens has remained stable in the five year period but has risen by one percent over the period to 85.8% of all screens in 2010, indicating that the number of women choosing to remain in the program has grown.

Figure 4: Attendance by screening round



Attendance rates by age group

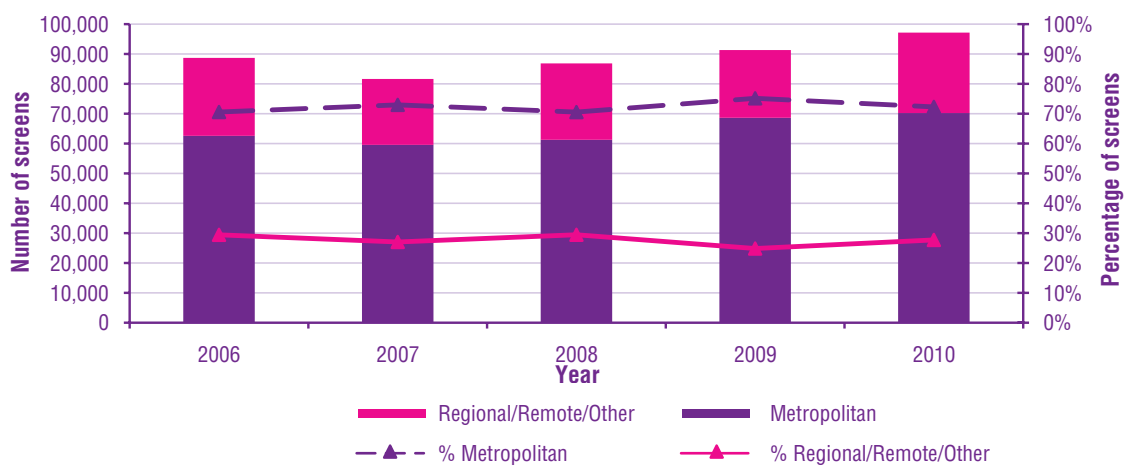
Women in the target age group of 50-69 years are the focus of the recruitment campaigns and they make up the majority of screens. Only women in this age group are invited to attend the program although all women who attend are re-invited when they are due, up to the age of 70 years (Table 4). The proportion of women attending in each age group has remained stable over the five year period.

Figure 5: Attendance by age group

Attendance rates by place of residence

Around 70% of screened women are from the metropolitan area while 30% live in rural or remote areas (Table 5). Whilst the total number of women screened in both metropolitan and country areas generally increased over the 5 year period, the proportions of country women versus metropolitan women did not vary significantly. There is some variation from year to year as the mobile units travel around the state in their two-yearly visit cycle.

Figure 6: Attendance by place of residence



Cultural diversity

It is a feature of the Program that cultural diversity is represented in the women screened and that these women are not disadvantaged in their access to the service. Particular efforts are made to develop recruitment strategies to encourage screening among Aboriginal and Torres Strait Islander (ATSI) women and women from culturally and linguistically diverse (CALD) backgrounds. The service travels to remote areas of Western Australia and liaises with indigenous health organisations to present information sessions to community groups and provide transport for these women where the mobile screening units cannot reach their communities. Culturally appropriate resources are also produced and language barriers are minimised with assistance from translators or translated resource material at both screening and assessment clinics. BreastScreen WA also organises block bookings, where a group from a community or association can attend together, as some women may feel more comfortable attending a screening appointment in a convivial setting amongst friends.

Figure 7 compares the changes in 24-month participation rates of women aged 50-69 years in the two key special needs groups with that of the remainder of the population. The Aboriginal or Torres Strait Islander (ATSI) participation rates have historically been much lower than for the population as a whole (see Table 2) so BreastScreen WA works closely with communities to ensure the highest possible attendance in this group.

Indigenous women made up less than 2% of all women screened each year, with the proportion fluctuating in tandem with the visit of the mobile vans every alternate year through the far north and south eastern parts of the state, where ATSI populations are the greatest. The proportion of indigenous women screened in the 40-49 year age group is higher (27.4%) than the proportion in the general population (15%), whilst those in the 50-69 year (68.6%) and 70+ year (3.9%) age groups are lower when compared to the general population (Table 6).

The participation rates of culturally and linguistically diverse (CALD) women, a description based on the language other than English the woman speaks at home, exceeded that of the remainder of the population for all five years and showed the greatest growth over that period. The figures indicate that the service is regarded as appropriate and acceptable to these women.

Figure 7: Participation rates of women aged 50-69 years by cultural status

The proportion of CALD women has remained at around 13% of all screens (Table 7) through the period of the report. The percentages screened in each age group are similar to that of the population as a whole.

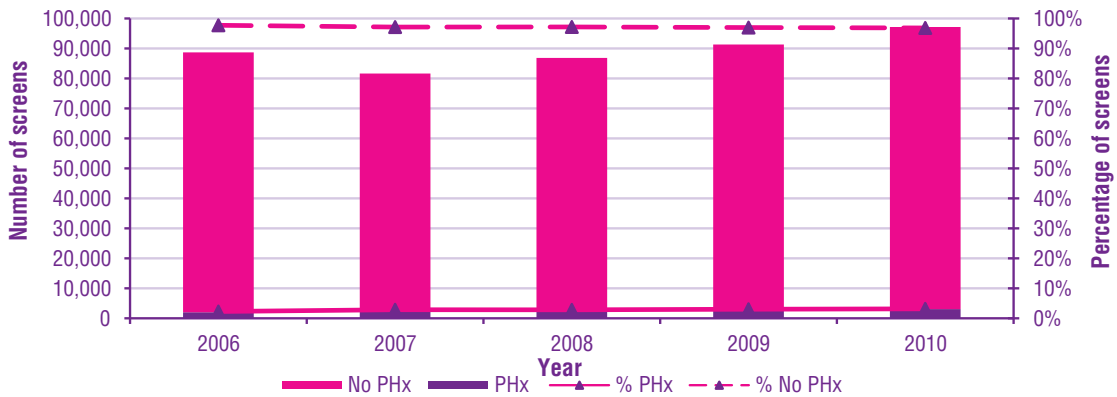
The most common languages spoken at home and the most common countries of birth are shown in Tables 8 and 9. Women speaking Italian at home made up the majority of screens in those speaking predominantly another language at home. Those born in England, Scotland, New Zealand or Italy comprised the top 4 countries of birth in foreign born screeners.

Women with personal history of breast cancer

BreastScreen WA offers annual screening to women who report a personal history of breast cancer. This number may include those who have had cancer diagnosed through the Program, those who have had a cancer diagnosed prior to their first attendance or those diagnosed with a breast cancer between screens.

Many women will return to the program after their diagnosis whilst others choose to have their future breast care managed by their surgeon. Although the proportion of women with a personal history of breast cancer grew over the five year period from 2.3% to 3.2% of all screens, the proportion of such women in the screening population remains small.

Figure 8: Attendance by personal history of breast cancer



Women with a personal history of breast cancer were more common in the over 70 age group (Table 10). The figures suggest that women use the screening process after their diagnosis and trust the program in looking after their future breast health.

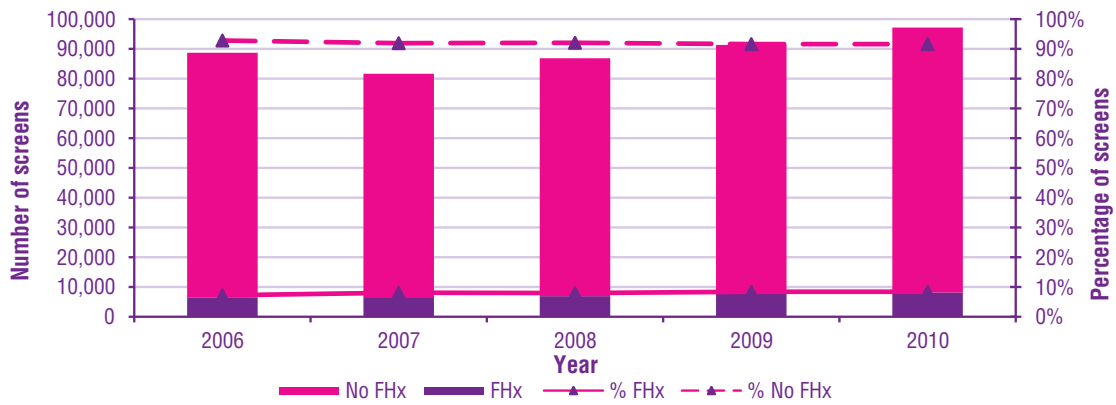
Figure 9: Women with a personal history of breast cancer by age group

Women with a family history of breast cancer

Since early 2006, only women with a significant family history of breast cancer - those with at least one first-degree relative diagnosed before the age of 50 years, two or more first-degree relatives diagnosed at any age, or a first-degree relative with bilateral breast cancer - are recalled every year for a screen. This definition reflects the National Health and Medical Research Council guidelines regarding individual breast cancer risk and means that women are not unnecessarily screened annually.

The proportion of all women screened annually for reporting a significant family history of breast cancer changed little between 2006 and 2010, making up between 7.2% and 8.4% of all women screened (Table 11).

Figure 10: Attendance by family history of breast cancer



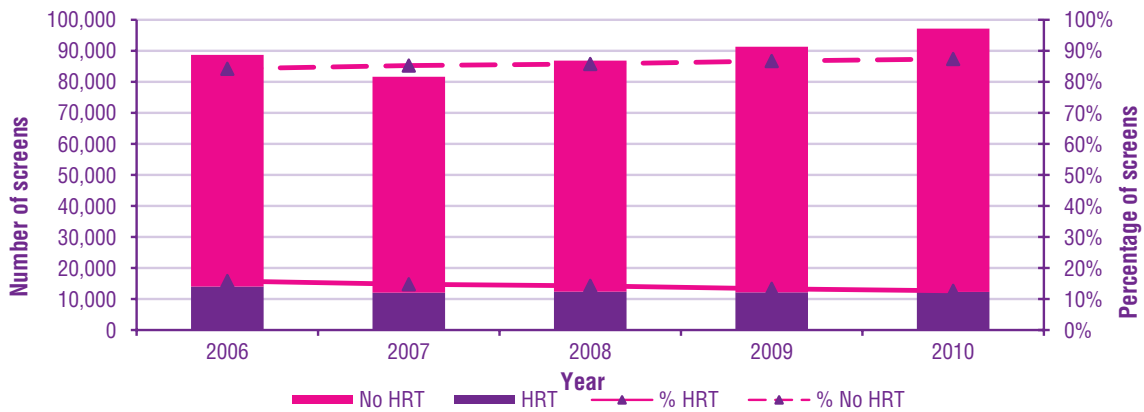
The proportion of women reporting a significant family history of breast cancer was highest in the oldest age group. However, those aged 40 to 49 years also made up a significant proportion for each of the five years in this period, indicating that younger women not targeted by the program were using screening to monitor their breast health where there was a family history of the disease (Table 11).

Figure 11: Family history of breast cancer by age group

Women who reported hormone replacement therapy use

The number of women who reported hormone replacement therapy (HRT) use at the time of screening decreased from 15.8% in 2006 to 12.6% in 2010 (Table 12). There has been a continuing downward trend following the announcement in July 2002 by the National Institutes of Health (US Department of Health and Human Services) that research had indicated that the use of hormone replacement therapy substantially increased the risk of women having breast cancer.

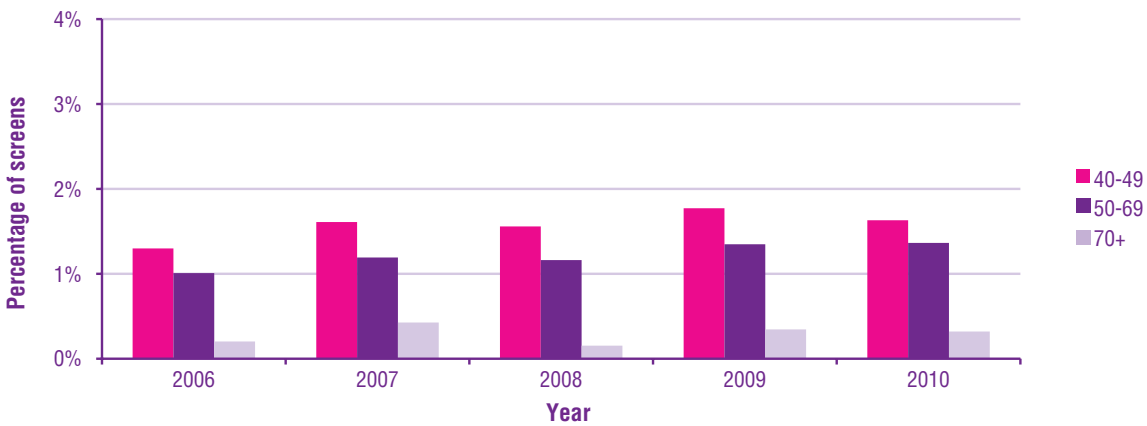
Figure 12: Attendance by HRT use



Women with breast implants

Women with breast implants (prostheses) made up an average of 1.2% of all screens from 2006 to 2010 (Table 13). Where implants are present, special views of the breast are taken as the prostheses can make it difficult to see areas of the breast, so the woman requires a longer appointment. When radiologists detect signs of silicon leakage on a mammogram, the woman and her general practitioner are notified in writing of the rupture.

Figure 13: Attendance in women with breast implants



Women with breast symptoms

The screening program is aimed at asymptomatic women as symptomatic women are more likely to have breast cancer and require more clinically focussed investigation to ensure an appropriate standard of care. Symptomatic women are discouraged from making a booking and encouraged to first see their doctor. Consequently, women attending with breast symptoms make up only 1% of all screens (Table 14).

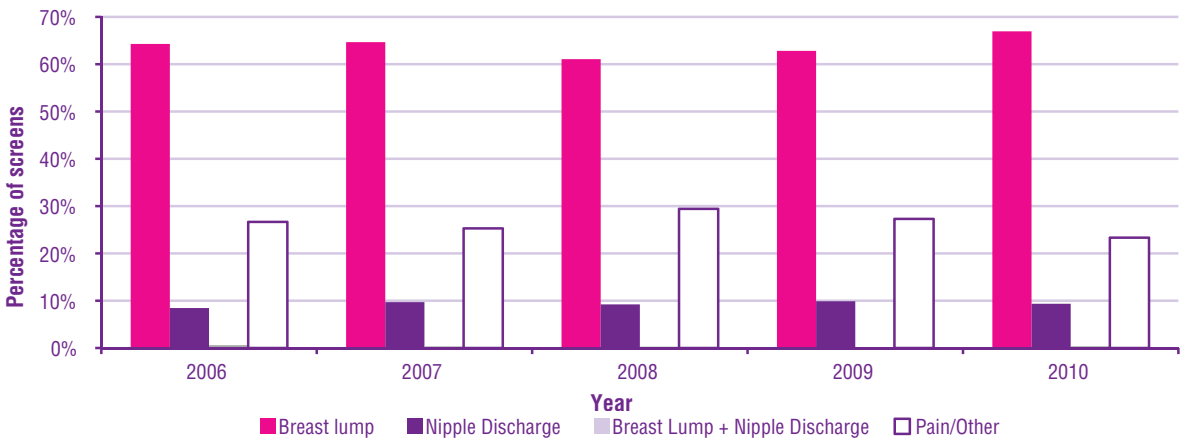
Figures 14 and 15 show the age groupings and symptom types for women attending with breast symptoms. Breast lumps, or serous or blood-stained nipple discharges are classified as significant symptoms, whilst breast pain or inverted nipple, for example, are not classified as significant.

As women are encouraged to become more "breast aware" and with occasional media articles on high profile young women with breast cancer, women attending for a screen with a breast symptom are more likely to be in the 40 – 49 year age group rather than those actively targeted by the Program.

Figure 14: Women reporting a breast symptom by age group

Most reported symptoms are breast lumps, with a smaller proportion of women reporting breast pain at the time of their screen. All women who report a symptom at the time of the screen, who indicate they have not had that symptom assessed by their general practitioner, are contacted by a Breast Assessment Nurse. Those with a breast lump or nipple discharge are recalled for assessment of the symptom, regardless of the outcome of the screening mammogram. Information relating to the assessment of the symptom is followed up by the program and entered in the data registry.

Figure 15: Proportions of breast symptom by type



Outcomes of Screening

NAS 2.6.1: <10% of women aged 50-69 years who attend for their first screen are recalled for assessment.

NAS 2.6.2: < 5% of women aged 50-69 years who attend for their second or subsequent screen are recalled for assessment.

The mammography images are read by two radiologists in a double blind mode. Two agree reads are required for the outcome to be a return to routine screening or for the woman to be referred for assessment.

Women may be recalled for a screen detected lesion or may present with a significant symptom which requires investigation. Figure 16 shows recalls for both mammographic and symptomatic reasons.

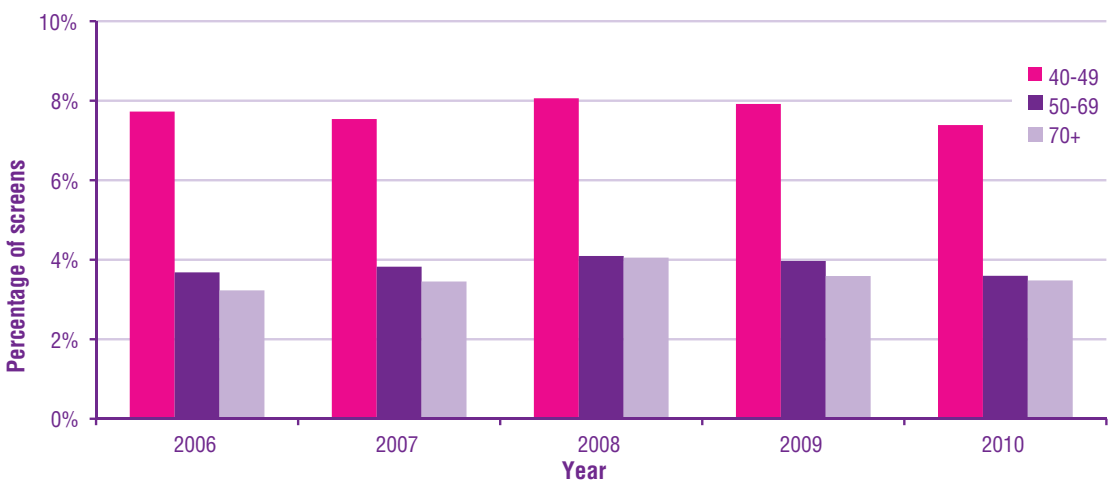
The NAS allows for women attending for their first screen to be recalled at a higher rate than women having a subsequent screen. This is because first screen women generally have no previous films to compare changes in the breast over time and the observed breast morphology may indicate a new suspicious change.

From 2006 to 2010 the majority of screened women (95.6%) across all age groups had a normal outcome with no lesion requiring assessment (Table 15).

On average, from 2006 to 2010, 7.7% of those aged 40-49 years were recalled for assessment, whilst 3.8% were recalled in the 50-69 year group and 3.6% in those aged over 70 years (Table 15).

The breasts in younger, generally pre-menopausal, women are denser and lesions are more difficult to distinguish from normal tissue, so recalls for further imaging are more common. In these breast types, benign lesions such as cysts and fibroadenomas are also more common. Younger women are also more likely to be attending for their first screen as they enter the eligible cohort, so their recall rate is also related to their screening round, as above.

Figure 16: Referrals to assessment by age group



The average recall rate over the five years for all women in the 50-69 year age group attending for their first screen was 10.5% and for those attending for a subsequent screen was 3.0%. Across all age groups the recall rates were 10.8% and 3.2%, respectively.

Figure 17: Referrals to assessment of women aged 50-69 years by screening round

Procedures

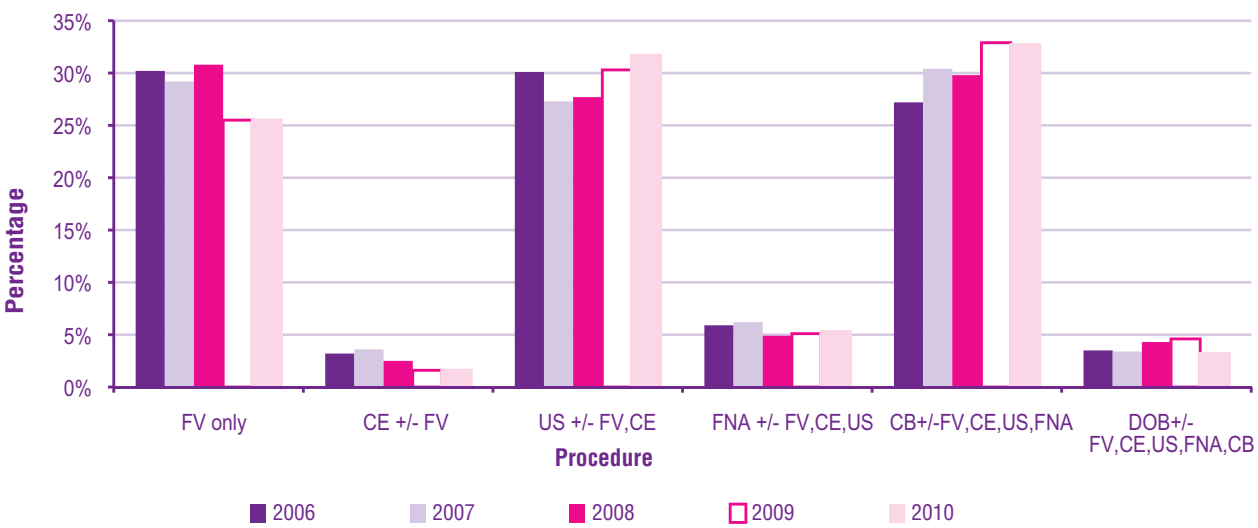
Procedures undertaken to assess a lesion or symptom include special mammographic views (diagnostic further views, DFV), clinical examination (CE), ultrasound (US), percutaneous needle biopsy (fine needle aspiration FNA, or core biopsy CB), or surgical biopsy (diagnostic open biopsy DOB). Women requiring assessment are invited to attend one of the two BreastScreen WA multidisciplinary assessment centres, at the Sir Charles Gairdner Hospital and the Royal Perth Hospital. Women screened outside the metropolitan area on a mobile clinic can, for convenience, return to have their diagnostic further views on the van – referred to as step down assessment.

Women are most commonly referred for DFV and US, with most lesions found to be benign and the woman returned to normal screening. Analysis of the lesion may require a fine needle aspiration or a core biopsy. A surgical biopsy to determine the assessment outcome is not common, as best practice requires that lesions are diagnosed without unnecessary surgical procedures.

The average number of assessments performed per woman was 2.5 from 2006 to 2010. Figure 18 shows that core biopsy was the key biopsy procedure, performed in 14.5% of all assessments, as it provides accurate and adequate sampling. Since the introduction of the core imprint technique at Sir Charles Gairdner Hospital, involving a cytological assessment of the biopsy sample as a good predictor of the final histology, same day core biopsy cytology results can be given to the woman.

In the six years to 2005, the percentage of assessments using fine needle aspiration averaged 10.4%, but this has fallen to 4.9% between 2006 and 2010 (Table 16). In 1.5% of all assessments diagnostic open biopsy was performed in order to obtain a definitive outcome.

Figure 18: Assessment procedures giving a definitive outcome



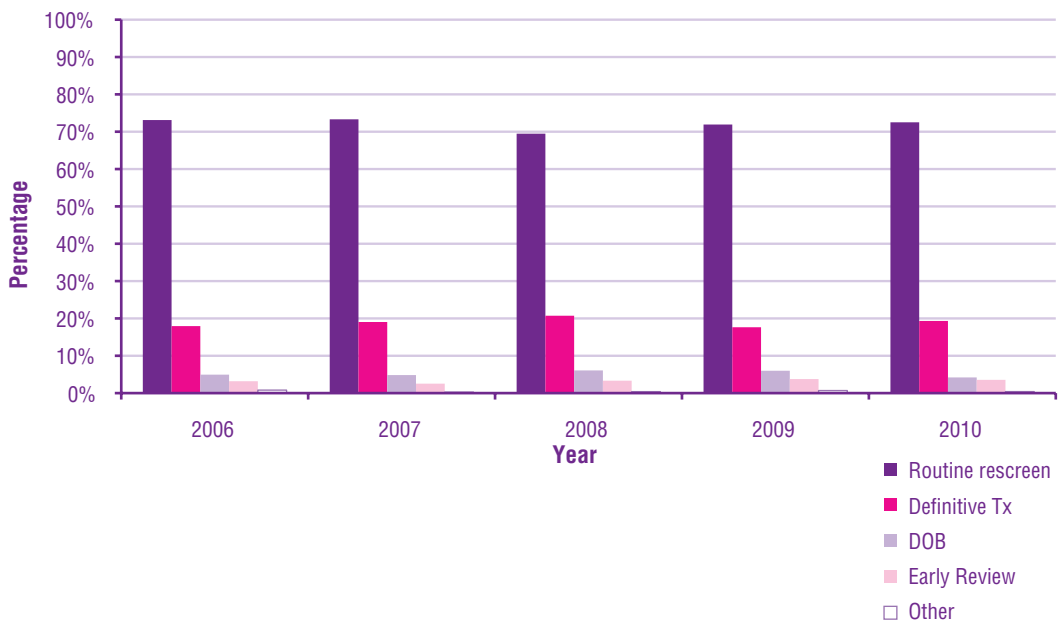
Recommendation after assessment

After the completion of her assessment, the woman is either given a recommendation to return to routine screening or to have definitive treatment for a malignancy.

Figure 19 shows that the overwhelming majority have a normal outcome and are returned to routine rescreen. An average of 18.9% of the women assessed were diagnosed with a malignancy without having to have an open biopsy (Figure 19, Table 18). This compares with an average of 11.1% for the previous six years, and reflects the improvements in cancer diagnosis using needle biopsy.

Only 5.2% of women were referred on for a surgical biopsy to obtain a definitive assessment outcome. In a small number of cases (3.3%) where a definitive result could not be obtained, the woman was asked to return in six months for a review of the lesion. A few cases were classified as "Other" where women chose therapeutic excision for a benign lesion, did not complete assessment or were assessed as having a leaking prosthesis requiring future monitoring by their specialist.

Figure 19: Recommendation after assessment

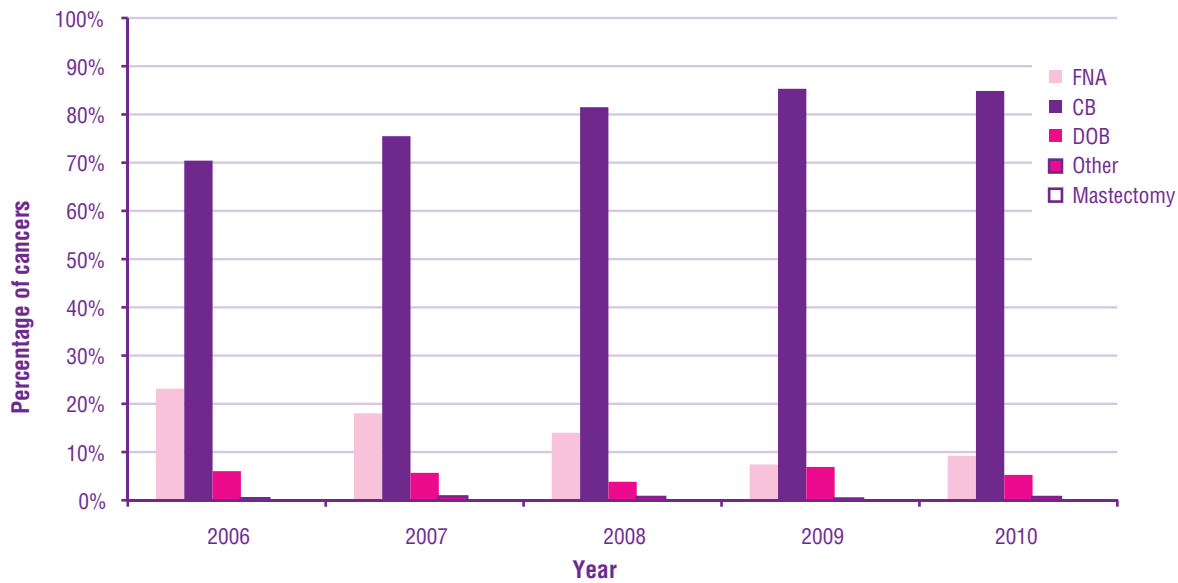


Breast cancer diagnostic procedure

NAS 2.7.1: ≥ 75% of invasive cancers or DCIS are diagnosed without the need for diagnostic open biopsy

BreastScreen WA aims to achieve diagnosis of breast cancer with a minimum amount of intervention and morbidity. Breast cancers were diagnosed predominately by CB, the proportion of which increased from 70.4% to 84.9% over the five years (Table 19). Correspondingly, diagnosis by FNA sampling fell from 23.1% to 9.2% as that procedure has lost favour as a diagnostic tool. Cancers diagnosed by DOB ranged from 3.8% to 6.9% in the same period. Fewer than 1% of cancers were detected by other means, for example if a needle biopsy yielded a highly suspicious result, the woman was referred for a therapeutic excision where a malignancy was diagnosed on pathology. No cancers were detected by mastectomy.

Figure 20: Procedure confirming breast cancer diagnosis



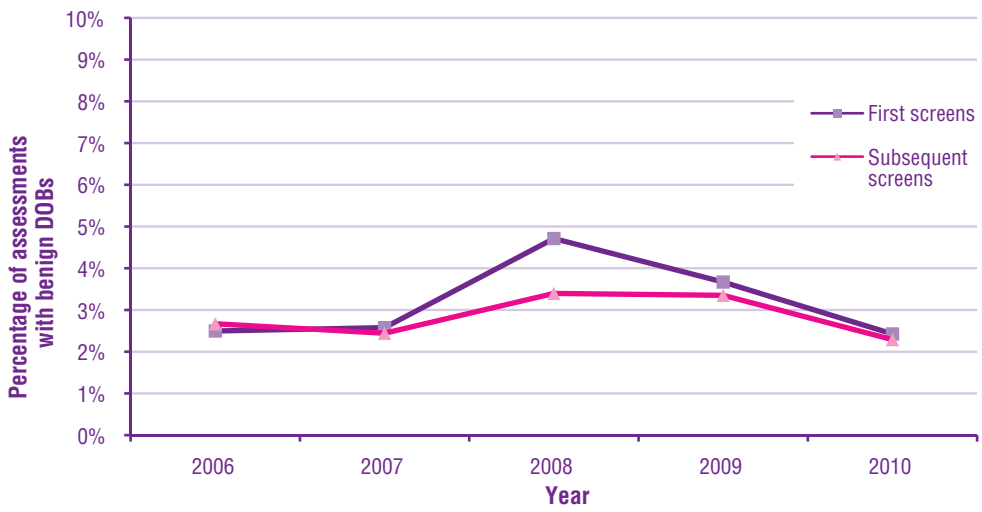
Outcomes of diagnostic open biopsy

NAS 2.8.3: ≤ 4.0% of women assessed after their first screen are found not to have invasive cancer or DCIS after a diagnostic open biopsy.
NAS 2.8.4: ≤ 3.2% of women assessed after their second or subsequent screen are found not to have invasive cancer or DCIS after a diagnostic open biopsy.

The Program aims to complete assessment without the need for surgery and to minimise the proportion of benign outcomes after surgical biopsy, thus reducing morbidity and minimising costly surgical procedures.

For the five year reporting period, the percentages of women assessed (Figure 21, Table 20) who had benign open biopsy outcomes were for most years within the National Accreditation Standards, averaging 3.1% for first screens and 2.9% for subsequent screens.

Figure 21: Benign DOB outcome in women assessed



Breast Cancer Detection Rates

NAS 2.1.1: ≥50 per 10,000 women aged 50-69 who attend for their first screen are diagnosed with invasive breast cancer.
NAS 2.1.2: ≥35 per 10,000 women aged 50-69 who attend for their second or subsequent screens are diagnosed with invasive cancer.
NAS 2.3.1: ≥12 per 10,000 women aged 50-69 who attend for their first screen are diagnosed with DCIS.
NAS 2.3.2: ≥7 per 10,000 women aged 50-69 who attend for their second or subsequent screens are diagnosed with DCIS.

For women aged 50 to 69 years, the invasive cancer detection rates over the reporting period ranged between 63 and 80 per 10,000 first screens and from 41 to 45 per 10,000 subsequent screens (Figure 22, Table 21). Ductal in situ cancer (DCIS) detection rates in first screens ranged from 12 to 27 per 10,000 first screens and from 10 to 16 per 10,000 subsequent screens (Figure 23, Table 21). Rates of cancer detection are higher in first screens, compared with subsequent screens where the breast tissue has usually been monitored regularly.

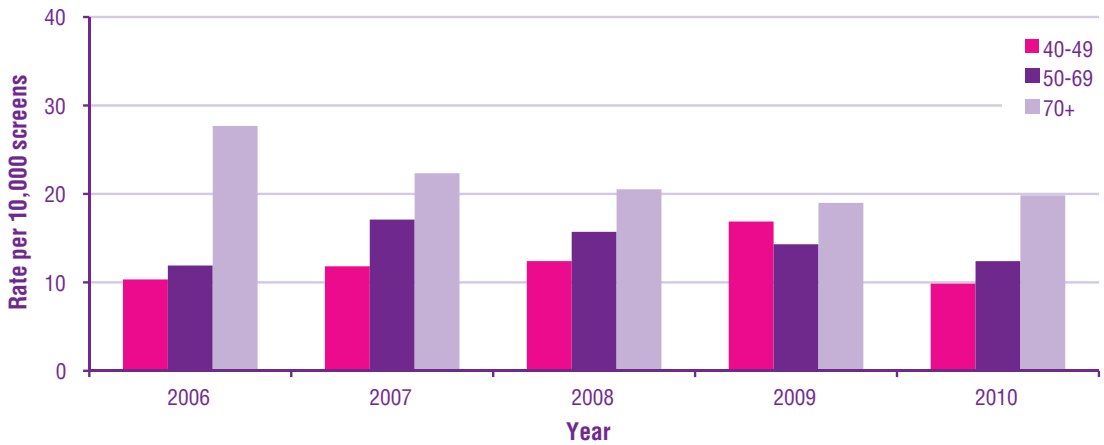
Figure 22: Invasive cancer detection rates in women aged 50-69 years by screening round

Figure 23: Ductal in situ cancer detection rates in women aged 50-69 years by screening round

The rates of cancer detection per 10,000 screens across age groups are shown in Figures 24 and 25. The rates of detection for both invasive cancer and DCIS were highest in women aged over 70 years for each of the five years.

Figure 24: Invasive breast cancer detection rate by age group

Figure 25: Ductal cancer in situ detection rate by age group



Cancer pathology

There were more invasive than in situ cancers detected for each of the 5 years of this report. The majority (80.4%) of invasive cancers were classified as invasive not otherwise specified (NOS), followed by lobular classical (9.7%) and tubular (3.6%) (Table 22). Of the ductal in situ cancers, about one third were comedo types, one third non-comedo and another third were mixed ductal types (Tables 23).

Size of breast cancers

NAS 2.2.1: ≥ 25 per 10,000 women aged 50–69 years who attend for screening are diagnosed with small (≤ 15mm) invasive breast cancer.

The aim of the Program is the early detection of breast cancers, that is, when they are still small and localised to the breast at the time of detection, with consequent lower morbidity and mortality. The small invasive cancer (≤15mm) detection rate is a key measure of the success of the Program.

From 2006 to 2010, the average rate of small invasive cancer detection in target age women was 28.6 cancers per 10,000 women screened (Table 24) with 60.1% of cancers detected in the target age group classified as small. The smallest cancers were detected in women attending for their second or subsequent screen (Table 25).

Figure 26: Invasive cancers in women aged 50-69 years by year by size

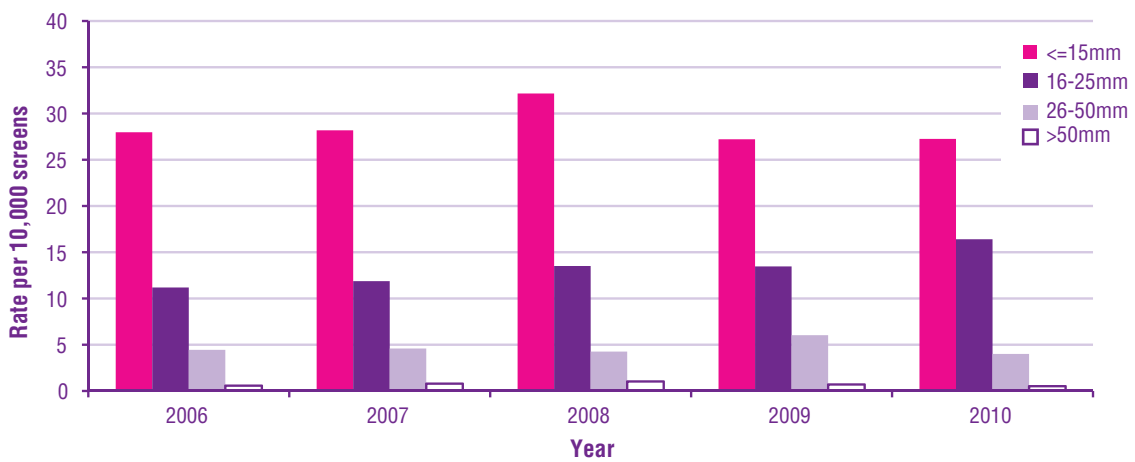


Figure 27: Average size of invasive cancers for women by screening round

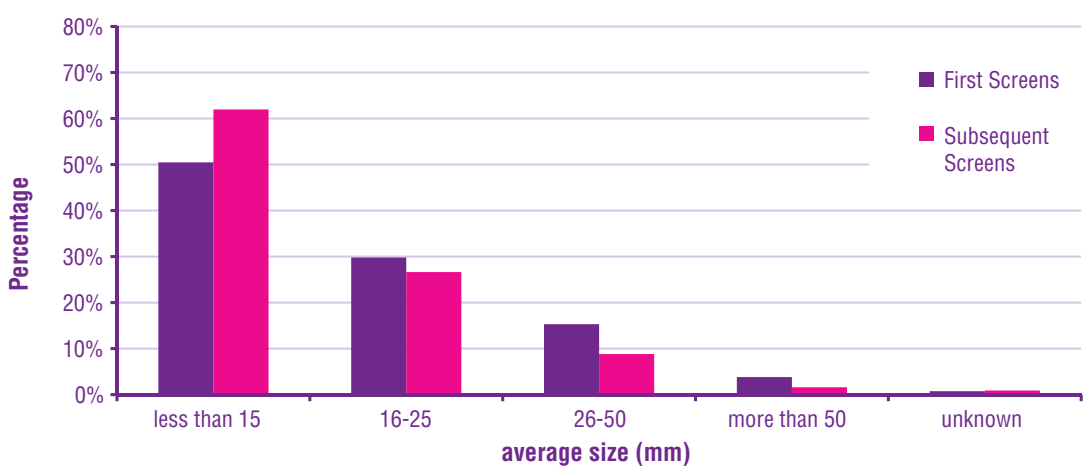
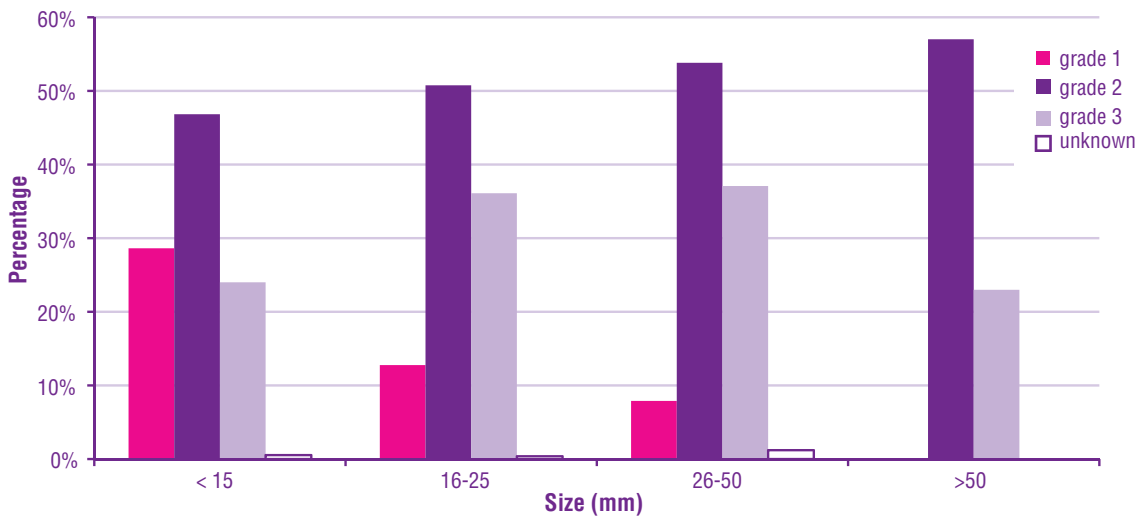


Grade of cancer

Invasive cancers can be graded according to their degree of cell differentiation, a good prognostic indicator. A high grade reflects a poorer prognosis and high grade cancers tend to be associated with larger cancers.

In general, the grade of the cancer increased as cancer size increased. The majority of the Grade 1 cancers were ≤ 15 mm in size, the size category into which most of the screen-detected lesions fell (Table 26). These results underlie the effectiveness of the screening program which is detecting breast cancers while they are small and low grade, hence reducing the morbidity associated with the disease and enabling a better prognostic outcome.

Figure 28: Average invasive cancer grade by cancer size

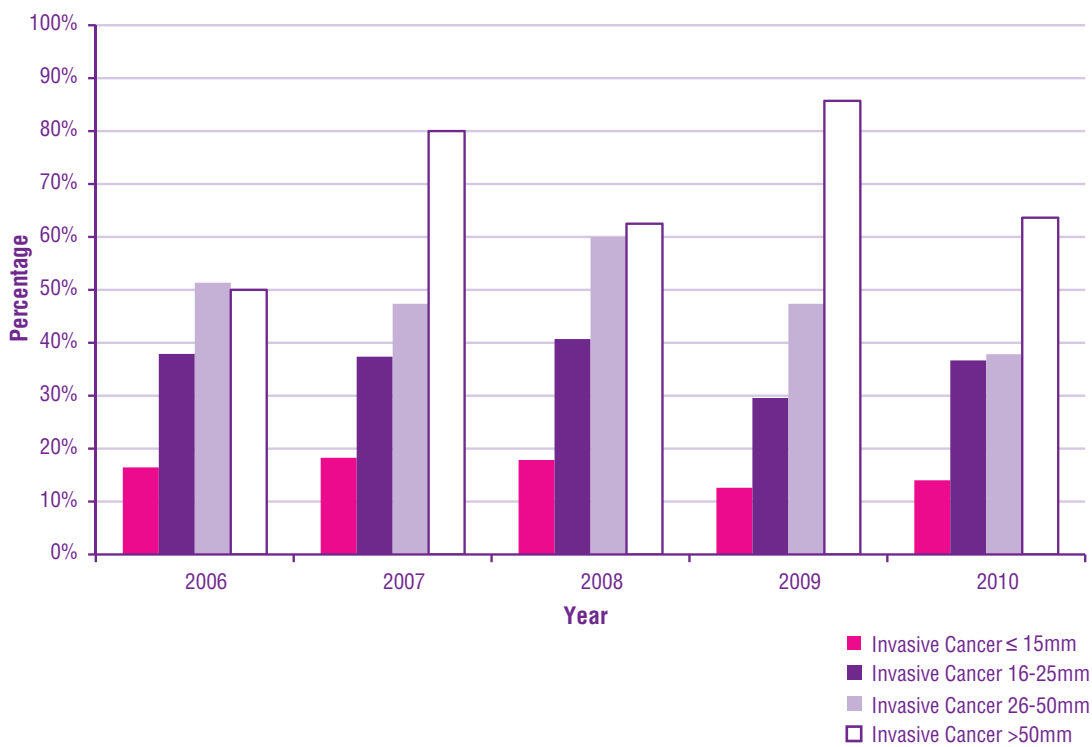


Nodal status

There is a strong association between lymph node metastases and the size of the breast cancer. Lymph nodes may be removed at surgery for the purposes of checking for the spread of the disease, which may include dissecting out all the axillary nodes. Selecting and examining the sentinel node for signs of metastases is now common practice and has meant that women need not undergo complete axillary dissection to confirm the spread of cancer cells. The sentinel node, localised using radioactive tracer or dye, is the first node or nodes which receive drainage from the breast tumour.

On average, over 95.8% of women diagnosed with invasive breast cancer had lymph nodes excised for examination (Table 28) and 26.0% of those showed evidence of metastases. The larger the invasive breast cancer, the greater the likelihood of finding the cancer has metastasised to the lymph nodes draining the breast. Over the five year period, the average percentage of lymph nodes that were positive for cancer ranged from 15.8% in cancers less than or equal to 15 mm in size to 68.4% in cancers greater than 50mm.

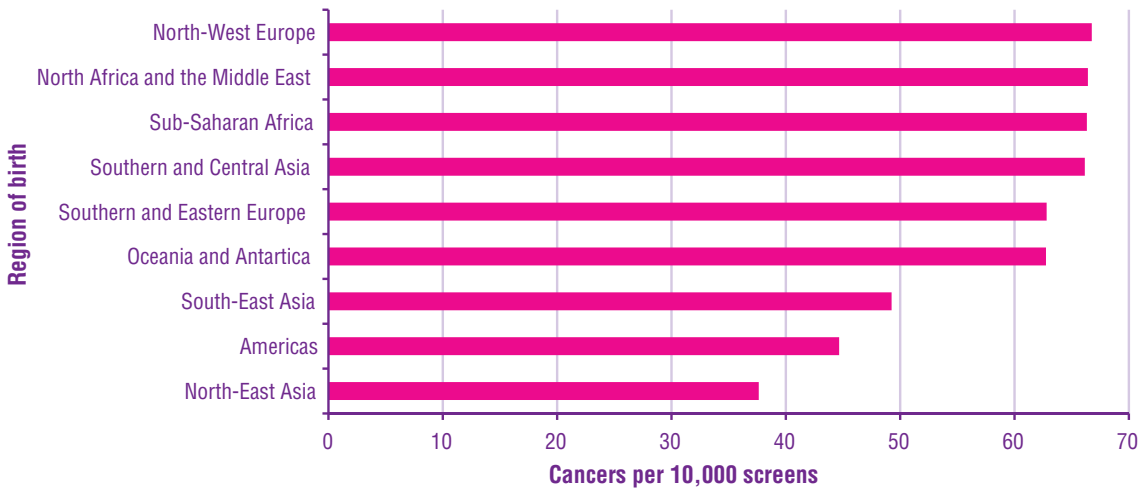
Figure 29: Positive lymph nodes by cancer size



Breast cancers by country of origin

There was no pattern in the rates of cancer detection by country of origin. Over the 5 year period, the regions most represented in the screen detected cancer group - Oceania/Antarctica and North West Europe - had some of the highest rates of cancer detection of over 60 per 10,000 screened, as did women who formed some of the least represented regions such as North Africa and the Middle East, and Sub-Saharan Africa. North East Asia, which includes Chinese Asia (including Mongolia), Japan and the Koreas, had the lowest cancer detection rate per 10,000 screens whilst comprising only 1% of all cancers detected in the period.

Figure 30: Cancers by region of birth



Breast cancers and family history of breast cancer

Whilst women with a significant family history of breast cancer made up an average of 8% of all screens in the years 2006 to 2010 (Table 11), they comprised an average of 9.5% of all breast cancers detected by the service in this period (Table 27). Women with a family history of breast cancer in the 70+ age group had the highest percentage of breast cancers detected with a rate of 13.1%, compared to 11.8% in those aged 40-49 years and 8.6% in those aged 50-69 years.

Surgery

The treatment of screen-detected breast cancers is not part of the BreastScreen Australia program. However, services collect details of any surgical treatment of breast cancer, which may be either mastectomy (M) or breast-conserving surgery (BCS), usually referred to as wide local excision. Figure 31 shows the proportion of women undergoing surgical treatment according to their cancer type. Figure 32 shows the surgical treatment type by place of residence. The majority of women underwent breast conserving surgery, with more than 60% of women undergoing the procedure regardless of cancer type or place of residence (Tables 29 and 30).

Figure 31: Surgical intervention for breast cancer by cancer type

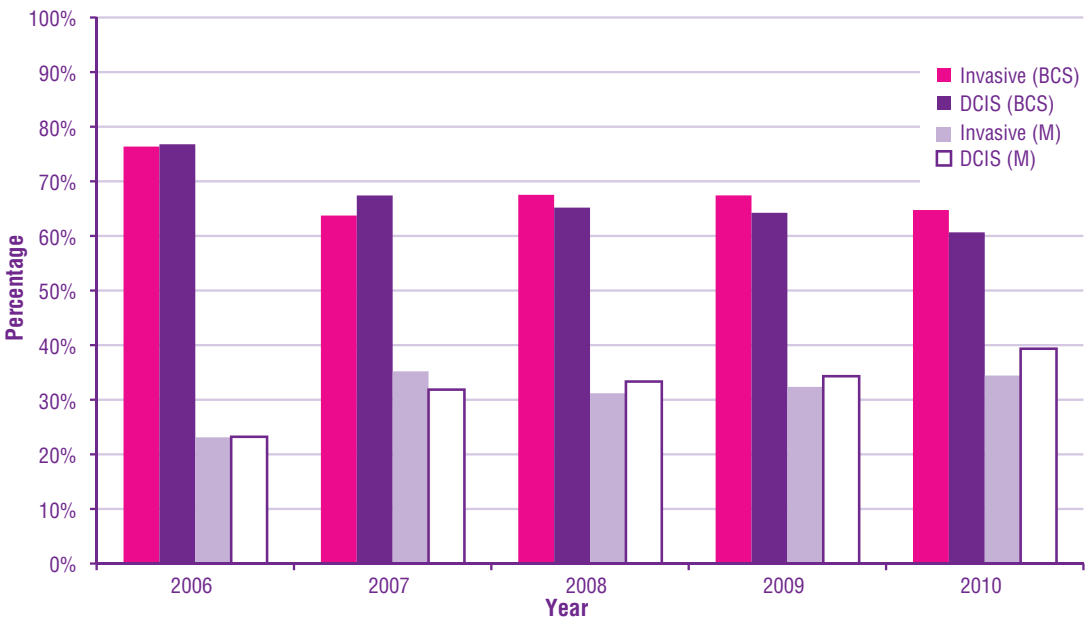


Figure 32: Surgical intervention for breast cancer by place of residence

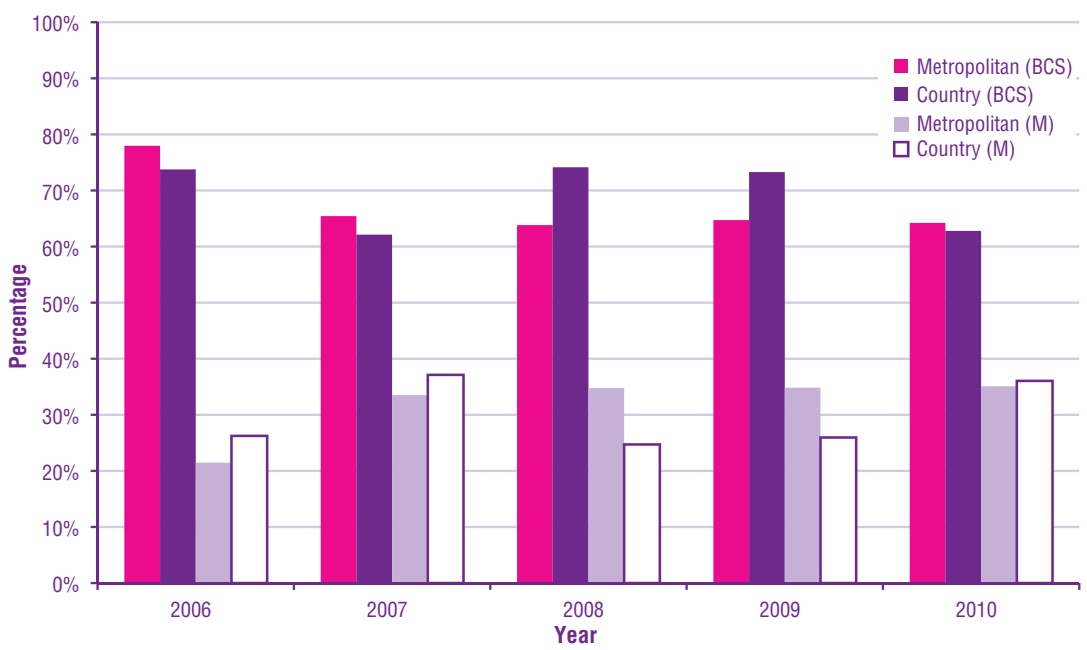
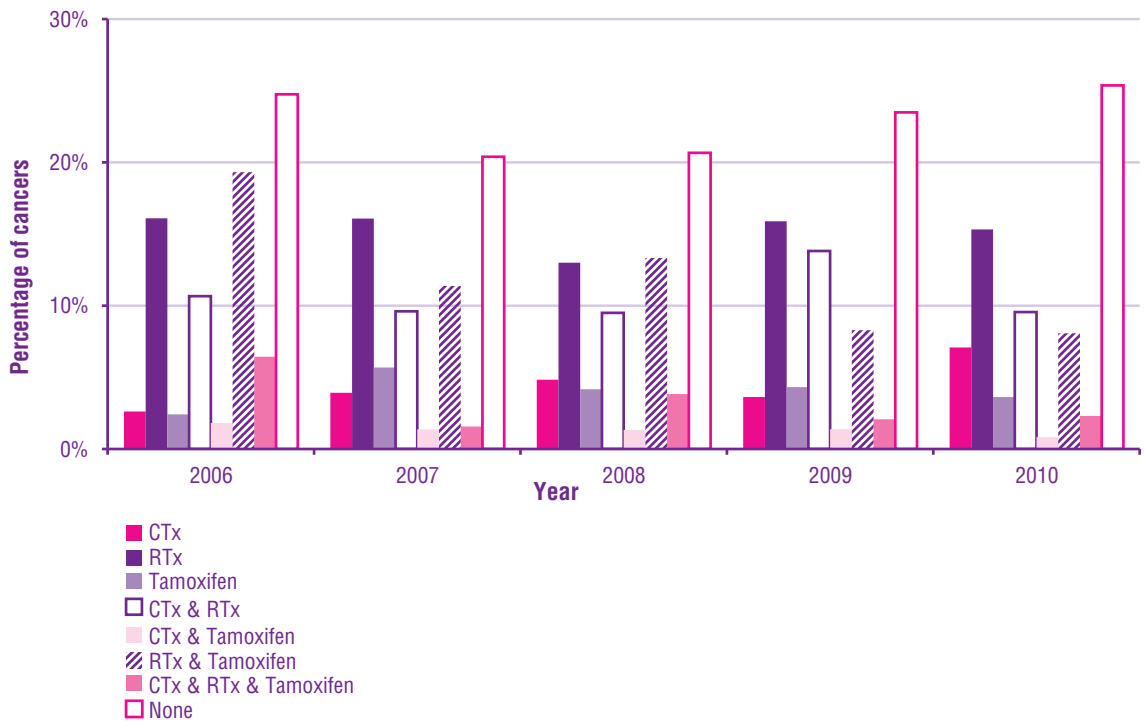


Adjuvant therapy

Adjuvant therapies available for women diagnosed with breast cancer include chemotherapy (CTx), radiotherapy (RTx), oestrogen receptor blockers such as Tamoxifen, drugs which block oestrogen synthesis such as Arimidex, or a combination of treatments. Figure 33 and Table 31 show the adjuvant therapies used for both invasive and in situ cancers and group these hormone blockers under the general heading of Tamoxifen. From 2006 to 2010 the combination of radiotherapy and anti-oestrogen drugs, or radiotherapy and chemotherapy, were the main treatments of choice for women with invasive breast cancer. For women with DCIS cancers the most common treatment was Radiotherapy, whilst more than 50% of women did not undergo any adjuvant therapy at all.

Figure 33: Adjuvant therapy for treatment of either in situ or invasive breast cancer



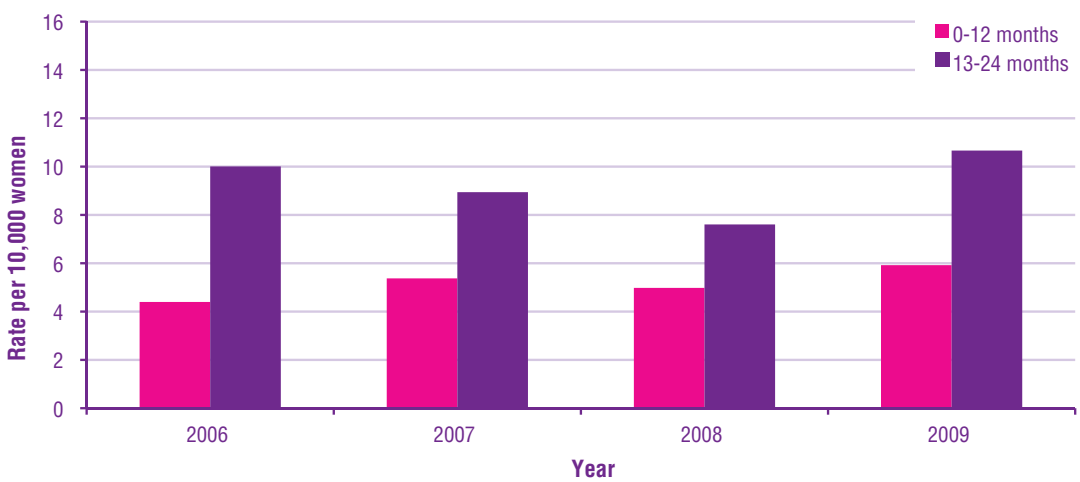
Interval cancers

NAS 2.4.2: < 7.5 per 10,000 women aged 50–69 years who attend for screening are diagnosed with an invasive interval breast cancer between 0 and less than 12 months following a negative screening episode.

Invasive cancers diagnosed in the interval between screening visits are called interval cancers. These cancers are identified through matching breast cancer data with the WA Cancer Registry or from notification by the client, her general practitioner or surgeon. Information is collected for the 12 months post-screen period for annual screeners and for up to 24 months for those recommended for screening every 24 months. The interval cancer rate is an important measure of the effectiveness of the screening process in identifying breast cancers.

The interval cancer rate for the period up to 12 months after a screen in the target group of women aged 50-69 was consistently below the national standard and averaged 5.2 women per 10,000 screens over the reporting period (Table 32).

Figure 34: Interval cancers in women aged 50-69 years by period after screening



Program sensitivity

A key measure of the effectiveness of the Program is the proportion of screen-detected invasive breast cancers found as a proportion of all invasive breast cancers found in the group, referred to as the sensitivity of the Program. BreastScreen WA has achieved a high level of sensitivity in target age women which has continued to improve over the reporting period, achieving the Program's aims (Table 33).

Figure 35: Program sensitivity for women aged 50-69 years by period after screening
