Foreword

BreastScreen WA has pleasure in presenting the Annual Statistical Report for the periods 2002/2003 and 2003/2004.

In 2002 the revised National Accreditation Standards were endorsed by BreastScreen Australia. Implementation of the new Standards necessitated that the service undergo a major review of policies and procedures to ensure the program complied with the new wide-ranging and expanded performance measures.

The program underwent both a successful data audit in May 2003 and a successful external accreditation site visit in October 2003 and was granted four-year accreditation in February 2004 by the BreastScreen Australia National Quality Management Committee.

As part of its review of activities, and in keeping with the focus of the new National Accreditation Standards, a comprehensive quality improvement review was undertaken by the service in preparation for accreditation. A new Quality Improvement Committee, approved under the Health Service (Quality Improvement) Act 1994, was established to undertake and monitor quality improvement activities service-wide, including clinical audits.

During 2003/2004, BreastScreen WA implemented a revised complaints management system with improved complaint recognition and reporting. Staff training was undertaken to enhance complaint recognition, reporting and management. It also implemented reporting of client clinical incidents as part of the Australian Incident Monitoring System.

Pressure on clinic capacity due to growing demand in the Fremantle area saw the January 2003 opening of the relocated Fremantle Clinic to larger premises at City House 22 Queen Street allowing a second mammogram machine.

Five mammogram machines at the Cannington and Mirrabooka clinics and the Outer Metropolitan, South East, and South West mobiles were replaced, ensuring a high quality technologically advanced mammographic service was available to Western Australia women.

In 2003 BreastScreen WA, in conjunction with the Cervical Cancer Screening Program, established an Indigenous Women's Reference Group comprised of indigenous health worker representatives from rural, remote and metropolitan communities. Following Indigenous community consultation, a statewide training package, containing culturally-sensitive health promotional resources and strategies, was developed to assist Aboriginal health workers to educate Aboriginal women about the benefits of regular cervical and breast cancer screening. A range of new Indigenous client health promotion resources was also developed.

A GP Liaison Officer was appointed in 2002 to promote awareness of breast cancer screening issues amongst GPs, to develop networks with the Divisions of General Practice and facilitate their collaboration and support of the Program. Courses have been developed to increase the GP's ability to diagnose and manage breast diseases in the community. These GP Up-skilling Courses, conducted as supervised Clinical Attachments at the breast assessment clinics, involve GPs attending five sessions to sit in with either a breast physician or breast surgeon.

Other key achievements during this period included the establishment of a new website, including extensive client information translated into 16 languages.

As Medical Director, I would like to thank the staff of the screening services, central co-ordinating unit and assessment centres for their enthusiasm, commitment, hard work and resourcefulness which allowed the service to grow and thrive during the reporting period.

Dr Elizabeth J Wylie (MBBS FRANZCR)

March 2007

About this Report

This BreastScreen WA Annual Statistical Report presents data for the program for two 12 month periods - from the 1st July 2002 to 30th June 2003 and from the 1st July 2003 to 30th June 2004. Data is presented side by side for each 12-month reporting interval, with some figures showing trend data over selected time periods. The Report includes information on the number of screens, the characteristics of the screened population, details of the assessments of any abnormality detected such as the procedures used and their outcomes, the pathology, size and metastatic status of identified cancers, and overall cancer detection rates.

The data is presented by age group or by screening round, with results for the target age group (50-69 years) highlighted. Throughout the Report, first screens refer to the first screen with BreastScreen WA even though some of these women may have had a previous screen outside the WA program. Subsequent screens include all those subsequent to the first screen for the time period reported.

BreastScreen WA's performance against a selected number of National Accreditation Standards is also presented. Compliance with these standards is critical to the success of the screening program and to the standard of care and quality of service BreastScreen WA offers the women of Western Australia.

General population statistics used as denominators for participation rates were drawn from the Australian Bureau of Statistics 2002 and 2003 Estimated Resident Population tables. The 2001 Census data was used to derive target population figures for Indigenous women from Aboriginal or Torres Strait Islander background, and for women who speak a language other than English at home, referred to here as women from culturally and linguistically diverse backgrounds (CALD).

BreastScreen WA thanks all staff and sessional clinicians for their commitment and dedication in helping the program attain the highest of standards and for the quality of the data collected and maintained in the Registry. Thanks also to the members of the State Accreditation Committee and others who have assisted in the production of this Report.

BreastScreen WA is a statewide population-based breast cancer screening service which is part of the national mammographic screening program, BreastScreen Australia, aimed at reducing morbidity and mortality from breast cancer through early detection of the disease. The program provides free high quality screening at 2-yearly intervals and targets asymptomatic women aged 50 to 69 years. Women aged 40-49 and over 70 years are also eligible to participate. Assessment of screen-detected lesions up to and including a definitive diagnosis of breast cancer or referral for diagnostic open biopsy is also part of the program.

To achieve BreastScreen Australia's aims it is critical for all services to maintain high standards of program management and service delivery. The National Accreditation Standards, revised in 2002, are a wide-ranging and comprehensive set of standards with a strong quality improvement focus and cover recruitment, screening services, follow-up of women with abnormalities, assessment services, data management and service management. Accreditation with BreastScreen Australia requires services to be compliant with the Standards, and in October 2003 BreastScreen WA achieved full four-year re-accreditation.

Service provision

The program aims to make the screening service available and accessible to all eligible women in Western Australia. There are seven clinics in the Perth metropolitan area and one mobile unit covering the south-eastern outer metropolitan area. Three mobile units service the south west, south eastern and northern regions of the state within a two-year cycle, visiting towns from Kununurra to Esperance and east to Laverton for periods ranging from a few days to twelve months (see Figures 1 and 2).

Women are invited to the program from the age of 50 years. Most women are screened every 2 years and sent a reminder letter when they are due. Only those women at high risk of developing breast cancer, such as those with a significant family history of breast cancer, a history of breast or ovarian cancer or other high risk breast changes, are invited for annual screens.

The State Coordination Unit (SCU) in Perth manages the appointment bookings, coordinating them with recruitment initiatives, clinic capacities and schedules, and is responsible for film reading, record and data handling and for mailing all invitation, reminder and result letters. The SCU also manages and reports on the financial aspects of the program, monitors and reports on program performance internally and to State and Commonwealth directorates and produces and coordinates the dissemination of all promotional materials.

BreastScreen WA provides assessment of screen-detected abnormalities up to definitive diagnosis at its two accredited assessment clinics located at Royal Perth Hospital and Sir Charles Gairdner Hospital. Breast Assessment Nurses inform women and their nominated general practitioner of the need for further assessment, organise appointments at the program assessment centres and offer support and advice to women regarding their assessment visit. Metropolitan clients are invited to attend one of the two assessment centres in Perth, whilst country clients may have their diagnostic further views done on the mobile unit. Some women choose to be assessed privately, outside the program, under the direction of their general practitioner. Information regarding the outcome of all assessments, including any treatments for cancer, is recorded on the database. Any anomalies or failures to attend for assessment are followed up by the service. The management of breast cancers detected during screening is not part of the BreastScreen WA program. However, information is collected for all cases of screen-detected cancers.

A range of recruitment strategies is developed by the SCU in consultation with consumer and health professional reference groups. Specific strategies are devised for recruitment through general practitioners and community groups, and for recruiting Indigenous women, those from culturally and linguistically diverse backgrounds and for women living in rural and remote regions of the state. Presentations are regularly made to ethnic groups and publications are available in a wide range of languages.

The service provides information and training to health professionals through educational activities such as a biennial breast cancer conference, communications workshops for general practitioners, and breast disease courses involving general practitioner attendance at 8 to 10 clinical sessions at the service's multidisciplinary breast assessment clinics. Screening-related articles are occasionally published in medical practitioner newsletters or journals and the service employs a GP Liaison Officer to assist in building partnerships with this group of health professionals.

Building strong alliances with the community and with health professionals is an important part of delivering a quality health service. It assists the service in providing accessible, acceptable and excellent health care, and in responding to and meeting the challenges of changing community needs and technical and medical developments.

Quality improvement

Accreditation with BreastScreen Australia involves thorough and regular review of all practices and outcomes in relationship to compliance with the National Accreditation Standards. Frequent auditing of processes and outcomes of both screening and assessment forms part of the program's routine quality improvement activities. Comprehensive and confidential individual performance management for radiologists is a particularly important part of the program's

activities, and is conducted quarterly by the Medical Director. Ongoing staff training, quality assurance of data held by the program and equipment and IT programming improvements are also part of the process of ensuring that BreastScreen WA offers the best possible standard of care and service to all women who take part in the program.

BreastScreen WA established a Quality Improvement Committee in early 2002 under the auspices of the Health Services (Quality Improvement) Act 1994. The Act grants special immunities and protections, including qualified privilege, for all activities and information gathered by the Committee. The main role of the Committee is to audit clinical and administrative practices, assess new technologies and oversee compliance with National Accreditation Standards with the aim of continually improving mammography screening services to the women of Western Australia. The Quality Improvement Committee's Annual Report to the Minister for Health reflects the service's focus on improving clinical and administrative practices.

Figure 1: Map of WA showing the towns visited by the mobile screening units

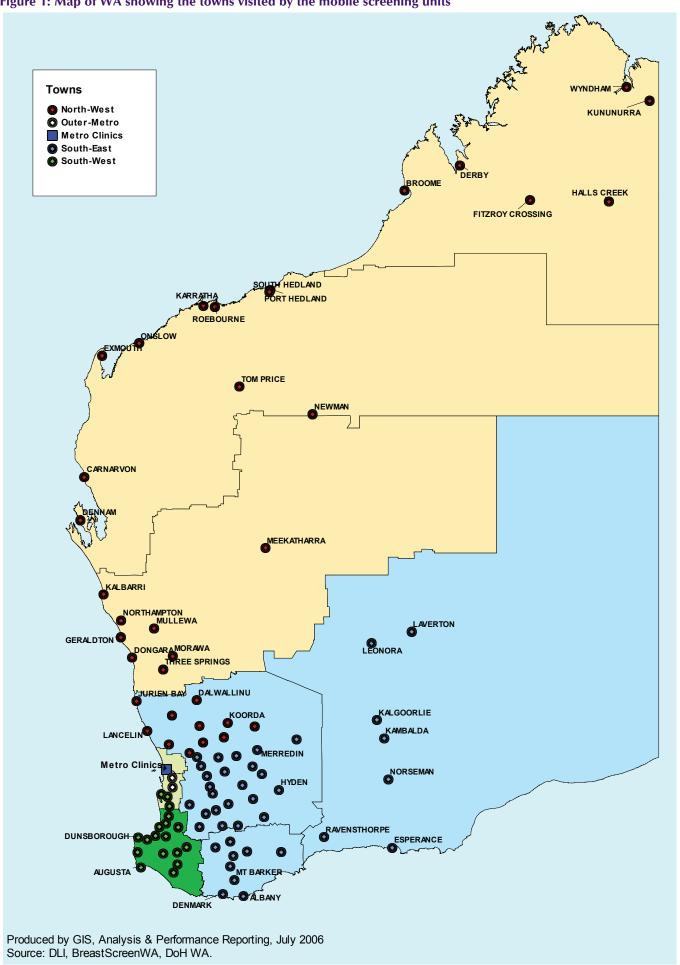

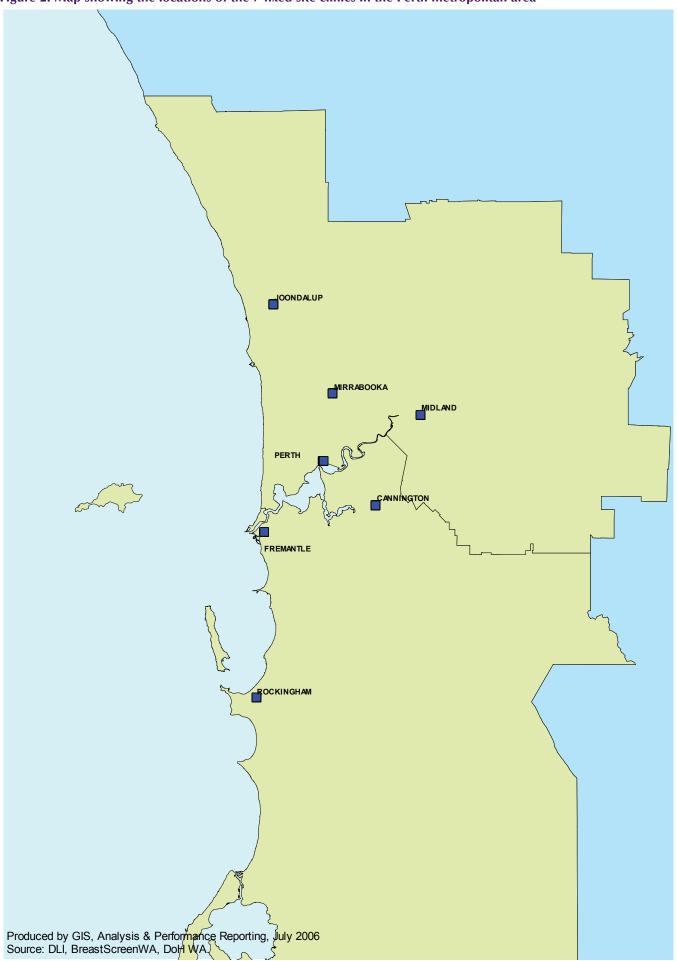

Figure 2: Map showing the locations of the 7 fixed site clinics in the Perth metropolitan area

BreastScreen WA Key Results for 2002/2003 and 2003/2004

Attendance

- BreastScreen WA performed 70,798 screens in 2002/03 and 80,315 screens in 2003/04. The percentage of women in the 50-69 years target age group was 77.6% and 77.8%, respectively.
- The participation rate for women aged 50 to 69 years was 54.9% for the 24-month period to June 2003, and increased by 1.7% to 56.6% for the 24-month period to June 2004.
- Of the women in the target age group, 58.2% of those screened in 2000/01 and 61.9% of those screened in 2001/02 returned for a rescreen within 27 months. Similarly, 73.7% and 77% subsequent screens in 2000/01 and 2001/02, respectively, returned for a rescreen within 27 months.

Demography

- Of all women screened in 2002/03 and 2003/04, 17.6% and 16.8%, respectively, were attending for their first
- Metropolitan residents made up 73.5% of women aged 50-69 years in 2002/03 and 75.7% in 2003/04.
- Indigenous women made up 0.9% (645) of screens in 2002/03 and 1.2% (949) in 2003/04.
- The proportion of culturally and linguistically diverse women was 12.7% (8,984) in 2002/03 and 12.9% (10,378) in 2003/04.
- A family history of breast cancer was reported by 17.8% of all women screened in 2002/03 and 17.6% in 2003/04.

Recall to assessment

- In 2002/03, 5.2% (3,698) of women were recalled to assessment 11.8% of initial screens and 3.8% of subsequent screens. In 2003/04, 4.8% (3,829) of all women were recalled - 11.1% of initial screens and 3.5% of subsequent.
- 4.6% of women in the target age group in 2002/03, and 4.1% in 2003/04, were recalled for assessment.

Assessment procedures

- On average, each woman recalled for assessment underwent two assessment procedures. Women requiring only further mammographic views, clinical examination and/or ultrasound to confirm an outcome of no significant abnormality comprised 61.6% of those assessed in 2002/03 and 62.2% in 2003/04.
- The majority of women assessed had a benign outcome 86.7% in 2002/03 and 86.9% in 2003/04.
- Of the 169 diagnostic open biopsies (DOBs) performed in 2002/03, 24.3% indicated a malignant lesion. In the following year 20.4% of the 142 DOBs indicated a malignant lesion.
- Of the 469 screen-detected breast cancers in 2002/03, 37.5% were diagnosed by fine needle aspiration, 53.9% by core biopsy and 8.3% by surgical biopsy. Of the 477 screen-detected breast cancers in 2003/04, 39.4% were diagnosed by FNA, 53.0% by core biopsy and 5.9% by surgical biopsy.

Breast cancer detection

- Of the 468 screen-detected breast cancers of known pathology in 2002/03, 344 (73.5%) were invasive and 124 (26.5%) were ductal carcinoma in situ (DCIS). In 2003/04, of 475 cancers, 367 (77.3%) were invasive and 108 (22.7%) were DCIS.
- The invasive cancer detection rate was 72 per 10,000 women aged 50-69 years who were having their first screen in both 2002/03 and 2003/04. For women in the target age group having subsequent screens, the rates were 48 per 10,000 and 44 per 10,000, respectively.
- In 2002/03 and 2003/04, interval cancer rates for women in the target age group were 7.5 and 4.5 per 10,000, respectively, for the 12 months following a normal mammogram.

Small invasive cancer detection

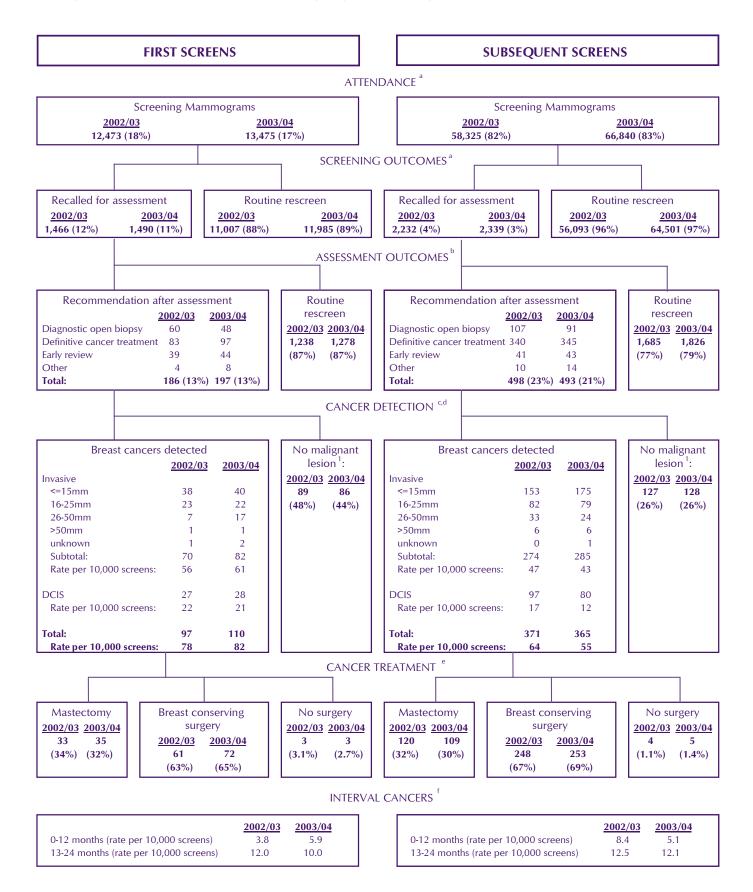

Where the size of the invasive cancer was known in 2002/03, 55.7% were 15mm or less. The small invasive cancer detection rate was 29 per 10,000 women screened in the 50-69 year age group. Of the 364 invasive cancers of known size in 2003/04, 59.1% were ≤15mm with a rate of 28 per 10,000 women in the target age group.

Treatment

Most women chose breast-conserving surgery - 65.8% in 2002/03 and 68.1% in 2003/04. In 2002/03, 34% of women with invasive cancer, and 29% with in situ cancer, had a mastectomy. In 2003/04 the figures were 30.2% and 30.6%, respectively.

BreastScreen WA Key Results for 2002/2003 and 2003/2004

The flowchart below summarises the outcomes of screening and assessment for women who attended for a screen from July 2002 to June 2004. It displays the information in two streams according to screening round - first screens or subsequent screens, for each 12 month financial year period from July to June.

SOURCE: a Table 14; b Table 17; c Table 21; d Table 23; e Table 27; f Table 31; 1 Benign outcome after diagnostic open biopsy, early review or other

Participation Rates

The BreastScreen program aims to achieve a greater than or equal to 70% participation rate for women in the target group of 50 to 69 years. Early detection leads to prompt intervention, resulting in a significant reduction of breast cancer-related morbidity and mortality. The participation rate is measured as the proportion of women in the target age group screened at least once over a 24-month period.

There was a 1.7% increase in the overall participation rate of women aged 50 to 69 years from 54.9% in 2001-2003 to 56.6% in 2002-2004 as shown in Table 1. This growth has been driven by the increase in the participation of metropolitan women, as the country participation has remained unchanged for several years. In 2001-2003, the participation rate of country women in the target age group was 5.2% higher than for metropolitan women. By 2002-2004, the gap had narrowed to only 1.2% higher, reflecting the growing participation of these women in the metropolitan area. In 2003, the metropolitan Fremantle clinic moved to larger premises which allowed for greater screening capacity. For the participation to increase, the number of women screened must outstrip the population growth. The target population grew by 3.4% over this period.

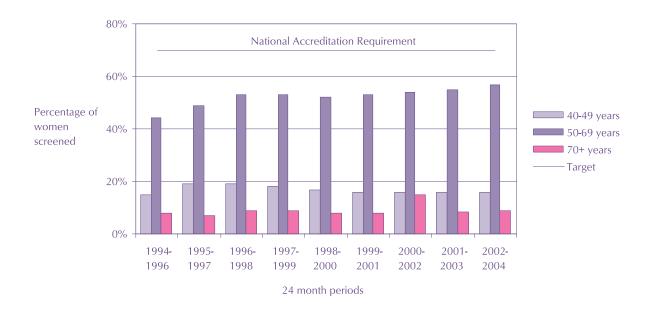

Table 1: Participation rates by place of residence by age , July 2001 to June 2003 and July 2002 to June 2004

Participation Rates

Figure 3 shows that from 1994-1996 to 2002-2004 there has been a steady increase in participation rates for women aged 50-69 years.

Figure 3: Participation rates by age from 1994-1996 to 2002-2004

The participation rate for Indigenous women in the target age group living in the metropolitan area was particularly low with 19.4% in 2001-2003 and 18.6% in 2002-2004, as shown in Figure 4. In contrast, Indigenous participation in the country was more than double the metropolitan rate with 46.5% and 49.0%, respectively.

Figure 4: Participation rates of Indigenous women by place of residence and by age, July 2001 to June 2004

Age group (years)

Participation Rates

The participation rate of culturally and linguistically diverse women (CALD) aged between 50 and 69 years and living in the metropolitan area was higher than the overall participation rate, reaching 61.5% in 2001-2003 and 66.3% in 2002-2004 (Figure 5). Fewer CALD women living in the country participated in the screening program compared with those in the metropolitan area in both 2001-2003 (50.1%) and 2002-2004 (52.1%).

80% 60% Percentage of women 40% screened 20% 0% 40-49 years 50-69 years 70+ years ■ 2001-2003 Metro 16.4% 61.5% 7.6% 15.0% 50.1% 8.8% ■ 2001-2003 Country ■ 2002-2004 Metro 17.3% 66.3% 8.8%14.1% 9.0% 52.1% ■ 2002-2004 Country

Figure 5: Participation rates of CALD women by place of residence and by age, July 2001 to June 2004

Age group (years)

The continuous challenge for BreastScreen WA is to promote the Service, have adequate capacity to accommodate the screenings and reach the target participation rate in a cost-effective way. Strategies are in place to encourage participation and cater for the needs of Indigenous women, CALD women, women with physical disabilities and those from rural areas or lower socioeconomic background. Invitation letters, printed materials in a range of languages, advertisements, interpreter services, community education and liaison with health professionals and extensive mobile unit coverage are examples of such operational strategies.

Demographic information such as place of residence, indigenous status and cultural background is collected to cater for any special needs required at screening and to provide information about the service's clientele. When a woman attends for a screening appointment, information is collected regarding personal history of breast cancer, family history of breast cancer, breast symptoms such as a lump or nipple discharge, presence of breast prostheses or use of hormone replacement therapy, as these may influence the interpretation of the films and the screening outcome.

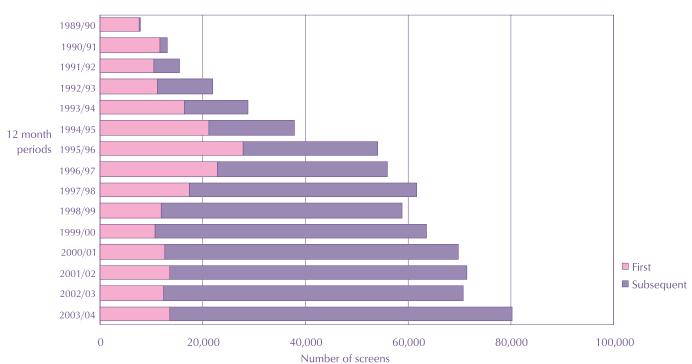

Type of Attendance

The number attending for screening has increased by almost 10,000 women from 2002/03 to 2003/04 as shown in both Table 2 and Figure 6. The proportion of women screened who are in the target age group has remained steady since 2001/02 (76.9%) - 77.6% in 2002/03 and 77.8% in 2003/04. In 2002/03 first screens made up 17.6% of all screens and in 2003/04 they made up 16.8% of all screens.

Figure 6: Number of screens by round by 12-month period between 1989/90 and 2003/04

Area of Residence

Table 3 shows that around three quarters of women screened in 2002/03 and 2003/04 resided in the metropolitan area. There was a 2.2% increase over this period in the proportion of metropolitan women screened in the target age group from 73.5% to 75.7%. The proportion of rural women aged 50-69 years being screened has fallen from 27.3% in 2001/02 to 26.4% in 2002/03 to 24.2% in 2003/04. Although the annual screening throughput in country areas is affected by the mobile unit schedules, declining population in some country areas, not necessarily reflected in the estimated population denominator, may also influence the figures.

Indigenous Women

In the 2001 Census, 1.4% (6,053) of all Western Australian women over the age of 40 years identified themselves as being of Aboriginal or Torres Strait Islander (ATSI) descent, with 41% being in the screening program target age group of 50 to 69 years and 68% living in rural and remote areas.¹

Over the two reporting periods there was a substantial rise in the total number of Indigenous women screened, from 645 (0.9% of all screens) in 2002/03 to 949 (1.2% of all screens) in 2003/04, as shown in Table 4. This difference most likely reflects the mobile unit schedules, where population make-up will vary across their routes over the two-year cycle. Nevertheless, these proportions in the screened population were lower than the proportion of ATSI women of the same age range in the general population calculated in the 2001 Census.

The proportion of ATSI women in the target age group increased from 62.0% to 66.9% of all ATSI women screened over the reporting periods, and was lower than that of non-indigenous women (77.7% and 77.9%, respectively) in both years. Women aged 40-49 made up a higher proportion of the ATSI screened population than they did in non-ATSI women, around 25% compared with 16%, respectively, for both reporting periods.

Women Speaking a Language Other than English at Home

According to the 2001 Census, 12% of West Australian women over the age of 40 years are from culturally and linguistically diverse (CALD) backgrounds, speaking a language other than English at home. Of the women screened in 2002/03, 12.7% were of CALD background, and in 2003/04 12.9% were of CALD background (Table 5), indicating that they are well represented in the Service's screened population.

Of the CALD women, those in the target age group made up around 78% in both reporting years. This was not greatly different from the proportion in that age group speaking English at home.

Table 6 shows the most common language spoken at home amongst women who attended screens in 2002/03 and 2003/04. Languages other than English commonly spoken at home are Italian, Chinese languages, Netherlandic, Croatian, German and Polish. Women speaking all other languages made up less than 7% of the total number of screens.

Personal History of Breast Cancer

Women with a personal history of breast cancer whether diagnosed at a previous screen with BreastScreen WA or detected outside the program are invited for annual routine screen. Table 8 shows that in 2002/03 and 2003/04 the service screened a similar proportion of women with personal history of breast cancer - 1,226 (1.7%) and 1,511 (1.9%), respectively.

Family History of Breast Cancer

Women were considered to have a higher risk of breast cancer if one or more of their first degree relatives (mother, sister, daughter, father, brother or son) were diagnosed with breast cancer. In the period covered by this Report, these women were invited annually for a screen. The Table below shows that 17.8% of women (12,602) in 2002/03 and 17.6% of women (14,136) in 2003/04 indicated a family history of breast cancer.

Since March 2006 women who have only one first degree relative with breast cancer, and where that cancer was diagnosed at age 50 or more, will be returned to biennial screening as they are deemed not to have a significant family history of breast cancer. The remainder will continue to be offered annual screening.

Women Reporting Symptoms at Screen

If a significant symptom such as a breast lump or nipple discharge (blood stained, clear or non-specific discharge) is mentioned at the time of booking, the woman is encouraged to consult her general practitioner first for a clinical examination. Women who present at screening with a symptom will be screened. Following a normal screen, they are followed up to encourage the investigation of the symptom. An appointment at Royal Perth Hospital or Sir Charles Gairdner Hospital assessment centres may be offered if the symptom has not been investigated by a GP.

Fewer than 1% of women reported a significant breast symptom at the time of screening as shown in Table 10. Women in the 40-49 year age group reported the highest proportion of symptoms, predominantly a lump, with 1.4% in 2002/03 and 1.7% in 2003/04. The category 'Pain/other' includes new, prolonged and/or severe pain or any other symptoms which are not considered significant.

Hormone Replacement Therapy Use

Hormone replacement therapy (HRT) use is associated with increased breast density, making interpretation of the breast x-ray more difficult. Information is collected at screening regarding any HRT use over the last six months. The use of HRT has fallen 6.2% in the screened population from 27.7% in 2002/03 to 21.5% in 2003/04 (Table 11). A similar trend was reported for women in the target age group with a drop from 31.2% to 24.1% in HRT use over this time period. HRT use was greatest in the 50-69 year age group.

Women with Breast Implants

Screening of women with breast implants is more complex. It requires special compression techniques and more views to be taken, and makes mammography less effective in breast cancer detection. Women are sent a pamphlet containing information about mammography and breast implants prior to their screen. In addition to the standard consent form, women are given another form that outlines the difficulties in screening and detecting abnormalities in breasts with implants. The notification of screening results to the women and their nominated GP contains advice about regular clinical breast examination. Table 12 shows that 0.9% of screens were in women with breast implants in both 2002/03 (661) and 2003/04 (692).

Rescreen Rates

The recommended interval for screening is two years. Annual screening is only recommended for women who have a family history of breast cancer, personal history of breast cancer or have previously been diagnosed with high risk breast changes such as atypical hyperplasias. The data in Table 13 includes women who have either a yearly or 2-yearly rescreen recommendation.

The National Accreditation Standards require that at least 75% of women in the target age group screened for the first time, and at least 90% of women in the target age group participating in their second or subsequent screen, return for a rescreen within 27 months. The 27 months period is set to allow time for women to respond to their rescreen letters. Table 13 shows that for screens in 2000/01, 58.2% of women in the target age group having their first screens, and 73.7% of women having second or subsequent screens, returned for a rescreen within 27 months. In 2001/02, 61.9% of women in the target age group having their first screens, and 77.0% of those having second or subsequent screens, returned for a rescreen within 27 months.

Outcomes of Screening

On completion of the screening film reading, the outcome will either be assessment required or return to routine rescreen. Referral for assessment is recommended if a suspicious lesion is found or a significant symptom reported at screen had not been previously investigated by the woman's general practitioner.

The National Accreditation Standards performance measure is that < 10% of women aged 50-69 years who attend for their first screen and < 5% of women aged 50-69 years who attend for their second or subsequent screen are recalled for assessment. The rationale for keeping recall rates low is to prevent any unnecessary concern for the woman, without increasing significantly the chance of missing an important lesion. According to results in Table 14, the majority of women screened were referred for routine rescreening. In 2002/03, 11% of women aged 50-69 years attending for their first screens were referred for assessment. In 2003/04, 10.4% of first screen target age women were referred. Of those women attending their second or subsequent screens, 3.7% in 2002/03 and 3.3% in 2003/04 were referred for assessment.

Assessment Procedures

When a woman is recommended for assessment, an appointment is offered at one of the program's assessment centres located at either Royal Perth Hospital or Sir Charles Gairdner Hospital. Alternatively, she may choose to be assessed privately. Women screened in the country areas are offered diagnostic further views on the mobile screening units. If further investigation is required, the woman is advised to attend the metropolitan assessment centres for further work up or have the lesion assessed privately via her GP. Procedures undertaken to assess a lesion or symptom include special magnified mammographic views, clinical examination, ultrasound, needle biopsy or surgical biopsy. All women, including those privately assessed, will be followed up to ensure a satisfactory outcome is achieved.

Diagnostic x-rays outside the program are classified as 'other mammography' as the full details of the films could not be obtained. 'Other mammography' may also include x-rays taken after an excision or needle biopsy, or x-rays taken at an early review visit.

In 2002/03 3,607 (5.1%) women, and in 2003/04 3,794 (4.7%) women, had one or more procedures as shown in Table 15. The number of women who had procedures at assessment does not equal the number of women referred as some women chose not to be assessed. A woman may have more than one procedure during her visit or more than one lesion assessed using different techniques. The average number of investigations per woman was two procedures, for both reporting years. Clinical examination and ultrasound remain the most common assessment procedures undertaken, making up 50.6% of all procedures in 2002/03 and 52.9% in 2003/04. Diagnostic open biopsy was carried out if the other procedures could not provide a definitive result.

The Definitive Diagnostic Procedure

A combination of procedures is usually required to reach a definitive decision at assessment. Data in Table 16 indicate the procedure undertaken before a return to normal screening was recommended or a definitive diagnosis was attained. In 2002/03 3,606 women, and in 2003/04 3,794 women, had one or more assessment procedures. One woman in 2002/03 did not have a definitive diagnosis from any of the procedures listed as she was undergoing chemotherapy treatment for other cancer metastases. In 2002/03 61.6%, and in 2003/04 62.2% of women required only further (diagnostic) views, clinical examination or ultrasound to reach a definitive outcome. For the two reporting years a fine needle or a core biopsy was required by 33.8% and 34.1%, and a diagnostic open biopsy by 4.7% and 3.8%, respectively, before a definitive diagnosis of benign or malignant was reached.

Recommendation after Assessment

At the completion of the radiological, clinical and needle biopsy stage of assessment, women are given an overall recommendation to return to normal screening, asked to return for a review of the lesion in 6 month's time (early review), recommended for surgical biopsy or referred to have definitive treatment for a malignancy. Those who chose therapeutic excision for a benign lesion, did not complete their assessments or had a leaking prosthesis where they will be under the future care of the surgeon were classified as "Other" in the accompanying Table 17.

Return to routine screening	2	978	1,436	590	91	7	2,026	79.4%	3,104	81.8%

The majority of women, 81% in 2002/03 and 81.8% in 2003/04, had a benign outcome of assessment and were returned to routine screening. More women having first screens were returned to routine screening (86.9% and 86.6%, respectively) compared to those having subsequent screens (77.2% and 78.7%).

In 2002/03 and 2003/04, 80 and 87 women, respectively, were required to return in 6 months for review of their lesion. It is desirable that women receive a definitive outcome of assessment at their first visit and that assessment is completed within 14 days. The National Accreditation Standards state that no more than 0.2% of women who attend for screening are recommended for early review. For both reporting years, early reviews comprised only 0.11% of all screens. An early review recommendation is made usually because nothing suspicious was noted at work up but there was still concern that the lesion needed watching.

The Definitive Diagnosis

Table 18 shows that of the women who attended assessment, 3,127 (86.7%) in 2002/03 and 3,296 (86.9%) in 2003/04 had benign outcomes, while 474 (13.1%) and 485 (12.8%) had malignant outcomes. For a large proportion of women with a benign outcome, a result was obtained after only requiring further views - 41.2% in 2002/03 and 37.1% in 2003/04.

In 2002/03, women attending for their first screen made up 39.5% of all women assessed and 20.6% of the breast cancers were detected in this screening group. In 2003/04 the proportions were similar: first screens made up 38.7% of all screens and 22.9% of the breast cancers. Four women in each year had non-breast cancers.

Procedure Yielding Pathological Diagnosis

The National Accreditation Standards require that ≥75% of invasive cancers or DCIS be diagnosed without the need for diagnostic open biopsies. Table 19 below shows that 91.4% (2002/03) and 92.4% (2003/04) of breast cancers were identified using non-surgical diagnostic methods via fine needle aspiration or core biopsy. Only 8.3% and 5.9% of women, respectively, in the two reporting periods required surgical biopsies to confirm a diagnosis of cancer. Over the last eight years, from 1996/97 to 2003/04, diagnostic open biopsies as the definitive procedure for breast cancer diagnosis have fallen from 36% to 6%, whereas the proportion of cancers detected by core biopsies has progressively increased from 13% to 53% (Figure 7).

Figure 7: Method of pathological diagnosis 1996/97 to 2003/04

Diagnostic Open Biopsy Outcomes

BreastScreen WA provides diagnostic open surgery at Royal Perth Hospital and Sir Charles Gairdner Hospital, or the woman may decide to have her surgery privately. Table 20 shows that 75.7% (2002/03) and 79.6% (2003/04) of all women having open biopsies were found to have benign lesions. The proportions were similar in the target age group, with 73.4% having a benign outcome in 2002/03 and 79.0% in 2003/04.

The National Accreditation Standards require that ≤4.0% of women assessed after their first screen and ≤3.2% of women assessed after their subsequent screen are found not to have invasive cancer or DCIS after a diagnostic open biopsy. Of the women assessed in 2002/03, 3.4% of first screens (48 women) and 3.7% of subsequent screens (80 women) had a benign outcome after a diagnostic open biopsy. Of the women assessed in 2003/04, 2.6% of first screens (38 women) and 3.2% of subsequent screens (75 women) had a benign outcome.

Breast Cancer Detection

Cancer Detection Rates

Table 21 shows the number of both invasive cancers and ductal carcinoma *in situ* (DCIS) detected in first and subsequent screens, by age group, and the rates per 10,000 screens. The BreastScreen program aims to detect at least 50 invasive cancers per 10,000 first screens and more than 35 per 10,000 subsequent screens in women aged between 50-69 years as key performance indicators of the screening program. The Program also aims to identify ≥12 DCIS per 10,000 first screens and ≥7 DCIS per 10,000 subsequent screens in target aged women.

In 2002/03, 474 cancers were detected through the program. However, 4 were not cancers of the breast, one was an interval cancer (a breast cancer detected in the interval between screening) and the other was of unknown pathology (lymph node metastasis where the primary site was unknown). Of the 468 breast cancers with known pathology, 73.5% were identified as invasive and 26.5% were DCIS. Invasive cancer detection rates in the target age group were 72 per 10,000 first screens and 48 per 10,000 subsequent screens. DCIS detection rates for this age group were 32 per 10,000 first screens and 16 per 10,000 subsequent screens.

In 2003/04 485 cancers were detected of which 10 were not classified as screen detected breast cancers. Cases excluded were 2 breast cancers of unknown pathology (no surgery undertaken because of advanced breast cancer), 4 non-breast cancers and 4 interval cancers. Invasive cancers made up 77.3% and DCIS 22.7% of all cancers. In the target age group, the invasive cancer detection rates in women having their first screens were 72 per 10,000 and subsequent screens were 44 per 10,000. DCIS detection rates for the target age group were 23 per 10,000 first screens and 12 per 10,000 subsequent screens.

Cancer detection rates were higher in women with a family history of breast cancer having their first screen, as shown from 2002 to 2004 in Figure 8. Family history over these time periods was as defined on Page 17 of this report. The rate of breast cancer detection in first screens in 2002/03 in women without a family history of breast cancer was 75 per 10,000, compared with 100 per 10,000 for those with a family history. In 2003/04 the figures were 75 per 10,000 and 131 per 10,000, respectively. Across all screens the differences in detection rates were minor.

Figure 8: Breast cancer detection rates by family history status, July 2002 to June 2003 and July 2003 to June 2004

Histologic Type of Breast Cancers

The table below shows the various types of invasive and *in situ* breast cancers detected by screening round. The most common invasive cancers identified were invasive ductal not otherwise specified, making up 74.4% of all types in 2002/03 and 76.3% in 2003/04. Comedo and non-comedo DCIS types were the most common *in situ* cancers.

Size of Breast Cancer

The detection rate of small invasive cancers is a key performance indicator as the aim is to detect cancers when they are still small and localised to the breast. The National Accreditation Standard defines small invasive cancers as those ≤15mm and sets a detection rate of at least 25 per 10,000 screens in the target age group of women. BreastScreen WA's small cancer detection rate for all age groups for both reporting years was 27 per 10,000 screens, as shown in Table 23.

Regardless of screening round, more than half of all invasive cancers were ≤15mm; 54.3% and 48.8% of first screens and 55.8% and 61.4% of subsequent screens, in 2002/03 and 2003/04 respectively. In 2002/03, 29 small invasive cancers per 10,000 screens in women aged between 50-69 years were detected (Table 24). A similar rate was reported in 2003/04 with 28 per 10,000 detected in target age group women.

Nodal Status

Lymph nodes excised during surgery for screen-detected invasive or non-invasive cancers were investigated for evidence of metastases. In 2002/03, 12.1% of women diagnosed with DCIS had lymph nodes removed during surgery (Table 25). None of the 15 lymph nodes excised showed any metastasis. The same was evident the following year where 18 (16.7% of DCIS) lymph nodes were excised and none showed metastasis.

More than 90% of women with screen-detected invasive breast cancer had lymph nodes removed and of these, 27.2% showed metastases. As indicated in the table below, lymph nodes excised from larger sized (26-50 mm and >50 mm) invasive cancers showed that the cancer cells had spread; 57.9% and 33.3% (2002/03) and 53.7% and 50.0% (2003/04), respectively.

Grade of Cancers

The grading of cancers depends on the degree of cell differentiation. The higher the grade, the poorer the prognosis. Grade 1 tumours are well differentiated, Grade 2 moderately differentiated and Grade 3 poorly differentiated. Almost 50% of invasive breast cancers identified in 2002/03 (43.8%) and 2003/04 (42.8%) were Grade 2 cancers. Figure 9 demonstrates the association between the size of cancer and its grade.

Management of Breast Cancer

Breast Cancer Treatment

The management of breast cancers detected during screening is not part of the BreastScreen WA program. However, information is collected for all cases of screen-detected cancers. For both 2002/03 and 2003/04, approximately two thirds of women chose to have breast conserving surgery, regardless of screening round, as shown in Table 27.

Table 27: Number of surgical procedures for breast cancer treatment by round, July 2002 to June 2003 and July 2003 to June 2004

	First scre	ens	Subsequent s	creens	All scree	ns

Table 28 shows the type of breast cancer and the surgical procedure chosen by women. The table does not include cases where the pathology was unknown. Most women opted for breast conserving surgery regardless of whether the cancer type was invasive or *in situ*.

Management of Breast Cancer

For metropolitan residents, the trend towards breast conserving surgery grew over the two periods from 62.8% in 2002/03 to 68.6% in 2003/04. For women living in country areas the reverse was the case, with breast-conserving surgery falling from 75.9% of all treatment in 2002/03 to 66.7% in 2003/04

Management of Breast Cancer

Adjuvant Therapy

In both reporting years, the majority of women with breast cancer had adjuvant therapy, with radiotherapy, chemotherapy or Tamoxifen alone or in combination. Both Tamoxifen, an oestrogen reception blocking drug, and Arimidex, a drug which blocks oestrogen synthesis, were in use at this time but both have been included in the Tamoxifen counts.

Radiotherapy and Tamoxifen in combination was the most common post-surgical therapy, comprising 29.9% of all adjuvant therapies in 2002/03 and 30.3% in 2003/04, and the most common post-surgery therapy in women with invasive cancers. The most common adjuvant therapy for women with *in situ* cancers was radiotherapy alone.

Fewer than half of the women diagnosed with DCIS in both reporting years had adjuvant therapy. However, the proportion has grown in the past 4 years – from 38.2% (2000/01) to 40.3% (2002/03) and to 45.4% (2003/04).

² includes Arimidex

Interval Cancers

Invasive breast cancers that are diagnosed in between a negative screening episode and the next scheduled screen are known as interval cancers. The term includes cancers diagnosed at early review after assessment. Information about interval cancers is obtained through a data matching process linking data from the WA Cancer Registry and BreastScreen WA and through notification by screening clients, surgeons or general practitioners.

Interval Cancers

Women recommended for annual screening are only at risk of interval cancers 0 to 12 months after a negative screen, and are therefore only included in the interval cancer count for those first 12 months. Those recommended for 2 yearly screening are included in the interval cancer count for both the first 12-month period as well as the 13 to 24 month period post-screening. Interval cancers rates per 10,000 screens are calculated as the number of interval breast cancers divided by the number of women years at risk.

The interval cancer rate is an important key performance indicator measuring the effectiveness of screening in identifying breast cancer. The National Accreditation Standards require that < 7.5 per 10,000 women in the target age will be diagnosed with invasive breast cancer in the 12 months following a negative screening episode. Table 31 shows the interval cancers detected for women screened in 2001 and 2002 and followed up for 24 months. The interval cancer rate for cancers detected up to 12 months in women aged 50-69 years was 7.5 per 10,000 women years at risk in 2001. This rate fell to 4.5 per 10,000 women years at risk in 2002.
